**The Need of Comet Observers.**—Dr. A. C. D. Crommelin has recently called attention to the small number of unexpected comets that have been observed in recent years. For example, in 1919 four of the five comets picked up during the year were returns of periodic comets previously known. Dr. Crommelin thinks that the scarcity of new comets simply means that few observers are hunting for them, and points out that there is an opening in this field for energetic amateurs.

**New Solar Observatory of the Smithsonian.**—The Astrophysical Observatory of the Smithsonian Institution has established a new station for the measurement of solar radiation on the Haqua Hala Mountains, near Wenden, Arizona, where the atmospheric conditions are said to be exceptionally favorable for such work. The observations at the new station, in conjunction with those made at the Smithsonian station at Calama, Chile, are expected to furnish interesting information concerning fluctuations in the solar "constant."

**The New Bulletin Astronomique.**—Since 1884 the Observatory of Paris has published a journal known as the *Bulletin Astronomique*, containing astronomical memoirs, observations, notes, and abstracts of current literature. This journal has now been divided into two distinct publications, one of which will be devoted entirely to abstracting. It is planned to publish the abstracting journal monthly as soon as the printing situation permits, but it has been begun as an annual, the first number covering the year 1919. The companion publication, bearing subtitle *Mémoires et Variétés*, will appear at irregular intervals.

**Lunar Photography with the Hooker Telescope.**—A few lunar photographs taken with the new Hooker 100-inch reflector of the Mount Wilson observatory have been so widely reproduced in magazines, in newspapers that some information concerning the circumstances under which they were made and the relation they bear to the general program of work at Mount Wilson will doubtless interest many readers. The pictures thus far published were obtained in the course of a wide variety of tests to which the new telescope has been subjected. They have been enlarged from negatives made at the Cassegrain focus of the telescope, where the equivalent focal length is 134 feet, corresponding to a diameter of the lunar image of about 11 inches. The exposures were about one-half second, reduced to a smaller fraction toward the much brighter limb by the exposing shutter moved before the plate. According to a statement by Director Hale, from which we gather these facts, there is no present intention of doing much work in lunar photography with the Hooker telescope, on account of the heavy demands of the regular program of research. This policy may, however, be modified in view of the recent action of the National Research Council in appointing a committee of geologists to examine the lunar photographs made at Mount Wilson and elsewhere and report what scientific results might be expected from a study of such documents, from the point of view of the expert in volcanology, topography, etc. Dr. Hale points out that few astronomers are qualified to study the moon's surface as a geological problem.

**More Views on Signaling to Mars.**—At the last annual meeting of the Kentucky Academy of Science, Prof. Henry Meier of Centre College set forth certain factors of the problem of signaling to Mars. In the first place, he said, the probably low temperature and rare atmosphere and the absence of water vapor (not, we would remark, universally admitted) are against the existence on the planet of beings endowed similarly to ourselves. Ability to signal by light is negatived by the fact that the earth's atmosphere would absorb about 40 per cent of the light sent out, and by the great distance. The author estimates that an area of light 10 miles square on earth, seen from Mars through a telescope magnifying 500 times, would appear like an area 1 inch square, viewed at a distance of 500 feet. The possibility of signaling by radio is negatived by the distance, it being computed that it would require a current of a million amperes at the sending station to obtain one of one ampere at a receiving station on Mars, when the planet is nearest the earth. Besides, the powerful currents radiated from the sun would probably overwhelm the weak waves sent out from the earth. While these objections are valid as far as they go, we would suggest that the real crux of the problem is the extreme improbability that a race of beings sufficiently "human" to hold any sort of intercourse with us exists on another planet. Once assume their existence, and it is easy to conceive them so far advanced in scientific attainments as to be in nowise dependent upon "a telescope magnifying 500 times" to catch our signals.

## Aeronautics

**An Aerial Survey of United States.**—Steps are being taken with regard to the making of a geological survey of this country by the aid of airplanes. The participation of New York State in the survey will necessitate about ten stations being established, or one for every 8,000 square miles. The estimated cost of producing the necessary photographic maps has been figured at anything from $5 to $10 per square mile.

**Increasing Popularity of London-Paris Route.**—The last figures which have come to hand with regard to the London-Paris air service indicate the steadily increasing popularity of that route. During July 933 persons so traveled, making a daily average of 30 passengers. The continuous increase in traffic is brought out by comparison with the number of passengers carried in February, 102; March, 183; April, 198; May, 450; June, 775.

**Sweden's Air Mail.**—We learn from our English contemporary *Flight* that an application has been made by the Swedish postal authorities to the Government for permission to establish a regular aerial mail route between Malmoe and Berlin, via Warnemuende. It is proposed that the service be maintained by German pilots on Junker machines, and it is stated that the consent of the Allies to this has been granted for a period of three months.

**New York to Alaska and Return.**—When the four airplanes of the U. S. Army Air Service Alaskan Flying Expedition touched ground at Mitchel Field, Long Island, on October 20th, the feat marked the completion of a flight over some 9,000 miles of uncharted territory in the last three months. The machines returned as spick and span as on the day of departure, July 15th. The machines were "DH-4-B" biplanes, made by the Gallaudet Aircraft Corporation of East Greenwich, R. I. Each plane was powered with a 400-horse-power Liberty motor.

**A Word About Baby Airplanes.**—From time to time a photograph appears, depicting a new airplane of compact dimensions and equipped with a low-power engine. Such airplanes are generally hailed as "everybody's" airplane and the coming "flivvers" of the air. Yet an examination of these machines soon discloses the fact that they are of little practical value. They are too small to be steady in flight, too low-powered to fly under moderately adverse conditions, too flimsy to last long, and, taking it all in all, absolutely worthless for serious work of any kind. They should generally be treated as novelties, except in rare instances.

**The World Flight.**—Aeronautic authorities have been busily engaged in formulating a fair set of rules governing the coming 'round the world flight. That aviators will not be permitted to take advantage of the rotundity of the earth is indicated by the condition that they must make their flights between the 15th and 60th parallels of latitude, and the prize will go to the flier who covers the longest distance. Aviators will be allowed to start from any point they choose, providing they return to the starting point. They will have a year in which to complete their flight. Airplanes, dirigibles, and free balloons are eligible for the race.

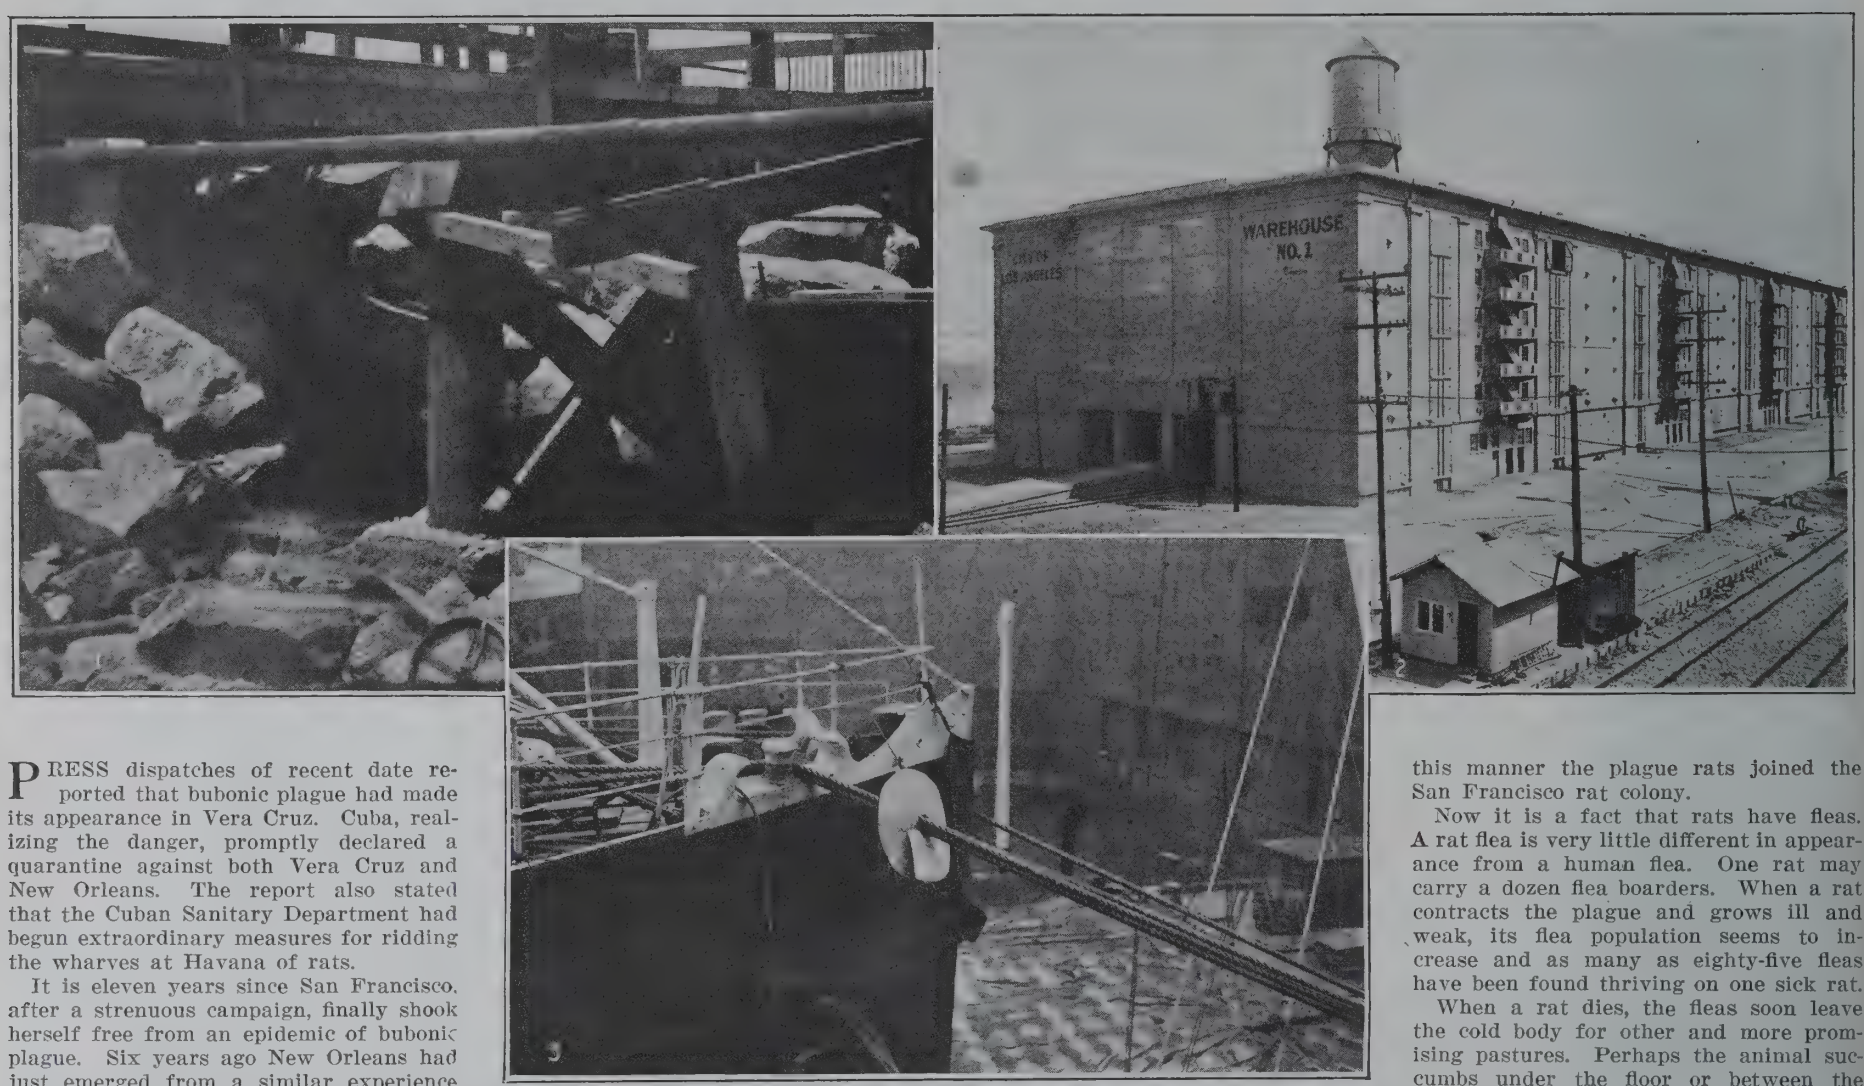
**More Accuracy, Please!**—If there is one thing which may be said against present-day aviation, it is that figures are handled in a loose way by those in and out of the art. Thus a new machine is said to make 225 miles per hour during a test flight, and yet the same machine, when flown over a definite course and with the proper officials at hand, fails to make anything like 200 miles per hour. There has been altogether too much loose talk about speed, climbing rate, carrying capacity, and so on, followed by such keen disappointment in actual performance that the art has suffered much criticism in consequence. Loose facts and figures and boasts do not win victories or make new records. Performance counts. It is time for all of us to stick more to cold facts and figures—and feats.

**Airway Upkeep.**—In the course of a statement in the French Chamber recently the Assistant Secretary of Aviation stated that the cost of upkeep of airdromes, hangars, repair shops, meteorological and wireless stations on the French portion of the Paris-London service was estimated at 20,000 francs per kilometer as against the cost of 50,000 francs per kilometer for a single line of railway. He thought that in future the total cost of organizing an aerial service would be 10,000 francs per kilometer. On the other hand, he emphasized the difficulties due to present heavy charges on flying plant, the French calculation of the life of an airplane being 200 flying hours, which meant that about 3.50 francs per kilometer had to be added to the total cost of the service. This, however, he had hopes of seeing reduced.

# Building Out the Bubonic Plague

## How the Twentieth Century Controls the Scourge of the Fourteenth by Waging War on Rats

By H. G. Adams



1—Entrance to a wharf before rat-proofing; the loose rock in the foreground was alive with the rodents. 2—A six-story wharf building of concrete and steel on a concrete dock with solid concrete foundations, affording no place for the rats to gain entrance. 3—Metal rat-guard on hawser of a ship in port

**Some of the means by which the prevalence of rats in seaport cities is checked in the war on bubonic plague**

PRESS dispatches of recent date reported that bubonic plague had made its appearance in Vera Cruz. Cuba, realizing the danger, promptly declared a quarantine against both Vera Cruz and New Orleans. The report also stated that the Cuban Sanitary Department had begun extraordinary measures for ridding the wharves at Havana of rats.

It is eleven years since San Francisco, after a strenuous campaign, finally shook herself free from an epidemic of bubonic plague. Six years ago New Orleans had just emerged from a similar experience with the black death. In both instances the scourge was not finally conquered until it was built out. This building out was accomplished by the use of concrete and metal in replacing old wooden wharves, sidewalks, basement floors and other harboring places of the rat.

The Citizens Health Committee of San Francisco, after completing its labors in connection with the epidemic, issued an extensive report of experience in fighting rats and stamping out the plague. Exceedingly interesting is the information contained in this statement: helpful facts that will be useful to other communities that find it necessary to make an organized effort against the same menace.

Among the activities of the Citizens Committee we find that 4,291,000 square feet of basements and floors were concreted; 1,190,000 square feet of concrete were laid in stables; 11,342 houses were disinfected and 1,713 destroyed; 3,967 stables were concreted, 903 ratproofed otherwise and 373 vacated; 5,000 chicken yards were ratproofed and 11,000 voluntarily vacated; and 676,000 square feet of chicken yards were graveled or concreted. The financial statement of the committee in itemizing some of the costs of this campaign, discloses some illuminating figures. It shows an expenditure of $4,012.42 for rat bait, which included 12,930 pounds of cheese, 5,042 pounds of bacon and 8,810 pounds of rat paste. Another item was for $1,438 to cover the cost of 14,608 rat traps. Bounties for catching rats at ten cents each amounted to $12,375.

During the first six weeks of the fight against the pestilence 56,994 rats were trapped or found dead. Thousands of others were washed out into the bay as a result of poisoned bait placed in the sewers. One week's rat catch amounted to 7,307. Of this number 2,382 were examined bacteriologically and 12 found to be infected with the plague.

The first visitation of the plague broke out in San Francisco in 1900 and it appeared again in 1907. The two epidemics claimed a total of 190 human lives before the malady was finally stamped out.

Just here it might be well to describe for the benefit of those who are not informed, how the bubonic plague is communicated to the human family. A vessel hailing from an Asiatic port tied up at a wharf on Frisco's water front. In the ship's hold lurked some bubonic-infected rats. Some of these little scourge-bearing messengers left the ship by creeping out along the huge rope hawsers that bound the vessel to the dock. In this manner the plague rats joined the San Francisco rat colony.

Now it is a fact that rats have fleas. A rat flea is very little different in appearance from a human flea. One rat may carry a dozen flea boarders. When a rat contracts the plague and grows ill and weak, its flea population seems to increase and as many as eighty-five fleas have been found thriving on one sick rat.

When a rat dies, the fleas soon leave the cold body for other and more promising pastures. Perhaps the animal succumbs under the floor or between the joists of a house. Some of the hungry fleas hopping about the floor land on the person of some unfortunate human. Bacteriologists have found that the gizzard of a flea may contain as many as five thousand bacilli of the bubonic plague. The flea can carry these about without any apparent ill effects upon its own health.

It is through the bite of the flea that the plague is transmitted from rat to rat and from rat to man. It was found during the epidemic at San Francisco that the plague attacked people who were in good health and living in sanitary, cleanly surroundings. One of the victims was the wife of a physician.

Fleas taken from a rat that had died of the plague were allowed to bite a guinea pig with the result that the animal at once became infected with the disease and died.

In San Francisco at this time, a man was found dead with the plague. The health officers ripped up the floor of the cottage in which he had been living and found a veritable honeycomb of rat holes. They also found several dead rats and the bacteriologists discovered upon examination that the rats had died of the disease. So the rat, tried and convicted, was sentenced to go.

One of the first steps in the program was to keep all garbage containers tightly covered. Measures were also taken to prevent food scraps from being scattered about. Where grain and meal stuffs were carried into buildings over gangways canvas was suspended beneath the trucks to catch the siftings, so that no rat food should be left on the ground. As an illustration of the importance of these small details, the last two bubonic rats caught in San Francisco were taken in a warehouse where they had been attracted by some fruit and nut culls left carelessly about. The rats had evidently entered by

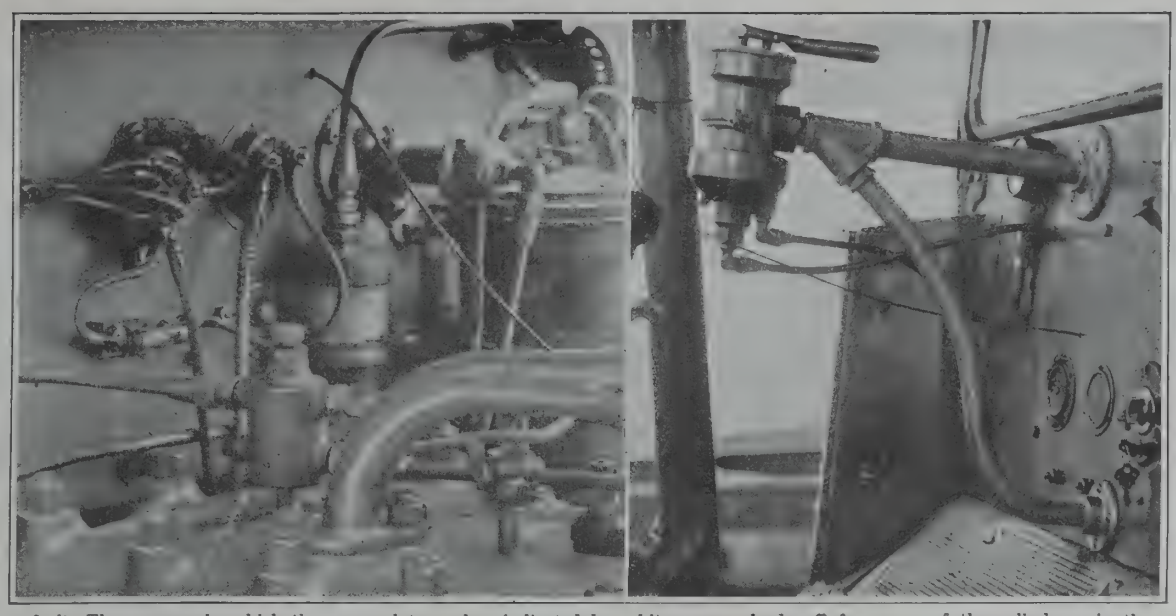
## Airbrakes for the Automobile

By C. W. Geiger

UNUSUALLY severe tests of automobile and truck brakes were made at the Safety First Exposition held in conjunction with the National Traffic Officers' Convention at San Francisco. The accompanying photographs show a system of air brakes for automobiles and trucks and trailers which proved to be nearly five times as efficient as the ordinary brakes. A five-ton truck and a five-ton trailer traveling at 18 miles an hour was stopped within 11 feet by means of the air brakes, the distance required to stop a truck and trailer equipped with the ordinary brake being 50 feet.



*Left:* The manner in which the accumulator valve, indicated by white arrow, leads off from one of the cylinders via the pet-cock opening. *Right:* The dash-board assembly from which the driver operates the new brake

**Two views of the air-brake outfit for motor-truck use**

This air brake system is of remarkable simplicity. It may be adapted to motor cars, trucks, trailers, semi-trailers and small industrial railways. It is flexible and may be used for operating the truck brakes only, or one or more trailers may be attached at any time and four-wheel brakes can be operated on trucks or trailers with a minimum of equipment.

Air pressure is obtained from one cylinder of the engine and is automatically maintained by means of an accumulator valve with only one moving part. Only a very small quantity of air (or spent gas) is taken at each stroke of the motor and only excess pressure can pass through the accumulator. When the engine is idling a pressure of 25 to 50 pounds per square inch is maintained in the tank but a laboring motor will raise the tank pressure to 200 pounds. The accumulator automatically stops when the tank pressure balances the pressure in the engine cylinder.

The control valve operates on an entirely new principle and is designed especially for the close regulation of brake pressure necessitated by the wide variation in loads, grades and road conditions. The brakes are applied by pulling the brake-valve lever toward the driver, the greater the movement the higher the brake pressure. To release the pressure move the lever back an amount corresponding to the effect desired. Quick return of the lever to full-release position exhausts the brake pressure through a quick-release valve which has only one moving part.

In order to insure instantaneous and complete response to the slightest variation in the brake-pipe pressure the brakes are actuated by a heavy rubber diaphragm in a bronze case. There is no leakage through a diaphragm and no friction is generated to resist movement at the least variation of pressure. No piston packing and no lubrication is required. The diaphragms are designed to apply more brake pressure with only 20 pounds of air than can be generated by the ordinary bandbrakes.

The system can be installed on any truck or trailer without any changes in the usual equipment and without affecting the operation of the ordinary brakes. The diaphragms may be mounted on each wheel or one for each pair of wheels, according to the type of truck. The system operates uniformly with full load, no load or even with broken springs.

The air-braking system is controlled by the driver with a small hand-lever, which is located just below the steering wheel on the support that carries the spark and throttle control. Directly in front of the driver is a gage which indicates the pounds per square inch pressure in the air tank, carried under the truck chassis alongside the frame, and also the amount of pressure per square inch used at each braking operation.

A line of air hose extends from the air tank to the brakes on the rear wheels of the truck and is then connected through regular air hose on the trailer. The action can be made to operate on the truck and trailer at the same time, or if the trailer is not used a valve on the rear end of the truck chassis is adjusted to control the air for braking on the truck alone. In the case of two or more trailers being used, the air arrangement is coupled progressively to the second and third, etc., and handled in just the same way. However, when more than two trailers are operated a specially designed air compresser is installed running off the drive shaft.

(*Continued on page 480*)

## Automobile Signals for Danger Spots

By G. H. Dacy

DURING a nine months' period last year, according to official reports of the Interstate Commerce Commission, there occurred 1,836 automobile accidents at highway grade crossings which resulted in the death of 923 persons while 2,554 people were badly injured. The grade crossing, the abrupt descent and the difficult and hazardous curve are the principal topographical and constructional hazards which jeopardize the lives and limbs of motorists in all sections of the country. Many danger signals and warning signs have been promoted and tried out but —for the most part—they do not efficiently serve the purpose for which they are designed.

Recently several ingenious signals of a new construction and type have been presented. The device of Charles E. Lyman, Asheville, N. C., appears particularly efficient and satisfactory. Briefly this signal consists of treads which are laid in the roadway in such a manner that as the automobile passes over them it presses down on a spring connection which completes an electrical circuit and lights a red lamp, rings a bell or sounds a horn in the roadway some distance ahead of the approachng motorist to warn him of a dangerous curve or crossing on the road ahead.

The operating part of the signal consists of two steel treads six feet long, three inches wide and 1¼ inches thick. They are hung on shaft ends at one edge and are braced underneath by five steel cross supports. The free edge of each tread is raised about ¾ of an inch by two 1¼-inch spiral springs placed underneath. The weight of the outfit is 600 pounds. At one end of the treads a double switch-box is installed, the outer of the two switch-boxes being part of the frame, while the inner is detachable and removable. The treads are separated by a parting strip.

The switch box contains two small shafts which engage at their inner ends by a coupling or tongue and groove arrangement with the shaft ends of the treads so that when the switch box is in position the depression of either tread operates the corresponding small shaft in the switch box. The main operating tread is at the right, the black saddle being used in order to give a better bearing surface for the wheels of the cars which pass over it. The left-hand tread is the silencer tread. Its function, when struck by a car going away from the danger point, is to throw the

(*Continued on page 480*)

*Left:* A suggestion in parking; it is as easy to back out as to run out forward, while it is much easier to go in forward than backward. *Right:* A new tread road-signal, with the operating tread at the right, and the disconnecting tread for cars coming in the safe direction at the left

**Two new illustrations of old ideas for street comfort and road safety**

# Succeeding in Illuminating Engineering

## What This Characteristically Modern Profession Holds Out to the Man Who Enters It

By Raymond Francis Yates

ILLUMINATION has an interesting history of development. It is only during the past few years that it has crystallized into a definite engineering science. It is no longer carried out by rule-of-thumb methods. The illuminating engineer has come into his own. He is today master of a science that is in its infancy. Many of the problems he has to contend with should have been solved years ago, but it is only recently that illumination has come to be regarded as the serious thing it really is.

It almost sounds unnecessary to say that this phase of engineering offers an attractive field for the young man. Any field of human endeavor that has just started to develop offers opportunity of the richest variety. Illuminating engineering is such a field.

Yesterday the lighting problem of a building was a matter of expediency. Today it is a matter of science. There is a scientific reason for doing things this way or that way in planning the lighting of a building. Illumination has always been just as important as it is today but it was just one of those things that no one recognized.

In preparing this series of articles the writer has always tried to obtain the ideas of a man of high standing in each field. The logical choice in the field of illuminating engineering was Mr. E. S. Doane, Chief of the Nela Research Laboratories at Cleveland, Ohio, and President of the Illuminating Society. Mr. Doane has reached the very highest plane of his profession and many of our lighting problems of today have been solved by his painstaking efforts and through his careful direction of the many experts who work under him. It is with a feeling of confidence that the writer gives Mr. Doane's ideas in the following paragraphs.

What is an illuminating engineer? One who studies lighting, of course, you say. Quite true, but many will be surprised to know that illuminating engineering is not recognized by our colleges at the present time. It is not because the field lacks the dignity of an established engineering science. It is because it is so young. In this respect it might be compared to radio engineering.

An illuminating engineer may be educated as a gas engineer or an electrical engineer. It is through special study that a man becomes capable of contending with the various problems of lighting as applied to streets, buildings, etc. This does not mean that any man without an engineering education cannot learn to apply the principles of illumination and become an illuminating engineer. If he desires to do this, he must first train himself in the fundamentals of either gas or electrical engineering. A sound knowledge of electrical engineering is the foundation of the application of illuminating engineering.

Mr. Doane describes an illuminating engineer and his work in these terms:

"I feel that illuminating engineering knowledge should be a part of the equipment of many different classes of engineers. Illumination is often referred to in two different senses: non-specific or general and specific.

"The man who designs general illumination, in which is included the lighting of public places, building interiors, etc., is usually primarily a gas engineer or electrical engineer, and usually also belongs to a subdivision of the general group. For illustration, he may be the engineer of electrical or gas distribution. I think in all such cases such a man becomes an illuminating engineer after having been trained as an electrical or gas engineer.

"The man who uses light specifically whether he be the engineer on a construction job, a mechanical engineer who builds his lighting apparatus in as a part of his design, whether he be an architect or whatever be his basic training, must many times in his career have charge of work, in which his knowledge of illuminating engineering would be of much value."

A curious public is just starting to be interested in the quantity and quality of light needed in various cases. The necessity of selecting the proper reflector, refractor and projector and placing in this light distributor the proper kind of lamp, is just starting to be recognized. Mr. Doane say that: "We are only just now approaching the time when work will be done under light chosen specifically for the particular kind of work on hand. I know of no other field of engineering that has been so long neglected. The usual factory is so lighted that work is not produced at maximum rate or of the best quality. We have demonstrated again and again that production and quality are improved under lighting which is technically correct. I know of no better way in which an operative can better his output in quality and quantity without added effort to himself and without new machinery," etc.

It would be difficult to find words that would impress one more with the great importance of illumination. It is a young field with a golden future. We are only starting to systematize our knowledge along this line. The work to be done is vast in bulk and important in nature. It will not only have to do with the conservation of human energy and the increasing of human efficiency, but also with the preservation of human eyesight, which is the most serious question of all. The lighting of the past has been a treacherous wrecker of eyesight.

When asked how a young man should educate himself to become an illuminating engineer, Mr. Doane expressed himself as follows: "The education one gets in college should be primarily to specializing in illuminating engineering. A real illuminating engineer must of necessity have other engineering knowledge. This should naturally be acquired before his illuminating engineering education. After that I know of no better way for a man to become informed as to his needs or to obtain the finishing touches of his education than through membership in the Illuminating Engineering Society. I believe that the same general qualifications required for civil, mechanical or electrical engineering are necessary to become an illuminating engineer although a man should have a greater knowledge of physics, especially as regards the physics of light."

When Mr. Doane was asked how far he thought an illuminating engineer should go in mathematics he became deeply interested. He maintained that mathematics is nothing but the shorthand of numerical reasoning. He looks upon it as a process which enables one to reason with exactness. We have learned that one cannot reason exactly and use values, without recording the progress of his reasoning from step to step.

How does salary run in illuminating engineering? For those who regard the answering of this question as being necessary it can be said that the salaries are about the same as those of electrical engineers. Experts in this line are able to demand high salaries, while from $3,000 to $5,000 is the usual salary for a man of ordinary standing in the field. The young man must always keep in mind that salary is always a measure of ability and not a denotement of profession.

Now comes the question of college. Can a man become a successful illuminating engineer without attending college? He surely can. The obstacles in this profession are no greater than in any other profession. It all depends upon the man. It would be advisable for a man with ambitions along this line to locate himself as an assistant in some of the big illumination laboratories.

Can an illuminating engineer go into business for himself? In one way he can. He can establish himself in the electric wiring business and in this way use and advertise his knowledge of illuminating engineering. Indeed it is regrettable that more of our so-called electricians are not capable of giving sound scientific advice on illuminating problems. Most of them are barely capable of intelligently using the new devices with which illuminating engineers have provided them.

Mr. Doane informed the writer that colleges are just beginning to show considerable interest in teaching the science of illumination. Through the efforts of the Educational Committee of the Illuminating Engineering Society, which is composed of professional educators, much progress is being made in raising the college course to a higher standing. Within a few years probably, our colleges will establish carefully developed courses in this new phase of engineering. The trouble is that so many new professions have developed within the past few years that our educational institutions have not had the time to develop courses.

What is the demand for illuminating engineers, is a question that the young man interested in this work is quite likely to ask. It is very easily answered. The demand far exceeds the supply, and any man thoroughly trained in this line of endeavor will find no trouble in locating with some well established organization.

This field does not seem to have reached the point as yet where specialists in any one of its particular branches are in great need. This does not mean that a man specializing in any of its branches will not find an opportunity to use his knowledge, whether he has specialized in street lighting or factory lighting. At the present time, and with manufacturers beginning to realize the importance of illumination as they are, it would seem that men specially trained to cope with the problem of factory illumination would find a fertile field to work in, with correspondingly good salaries. It is also true that a man specializing in the illumination of public thoroughfares would find good employment at a healthy salary if he is truly an expert. Municipalities are recognizing the lighting problem more than ever before and this country is annually spending hundreds of millions of dollars to light the streets of its cities. The author could name a dozen towns where one can stand in the center of the street at night and read a newspaper with ease, so perfect is the illumination.

As a final word. The young man who feels that this is an attractive field and that it satisfies his ambitions should not hesitate to dive into it. He cannot help but succeed. He can feel that he is growing up with one of the newest and most important engineering professions.

*THE great electrical works at Schenectady has a large department within its technical organization devoted exclusively to solving the problems of electric illumination and making new discoveries in this vital field. A glance at the advertising pages of any prominent publication of wide appeal will disclose many large concerns that deal in nothing but lighting equipment and handle none but lighting problems. The business of making night compete with day and indoors with outdoors is a characteristic of our modern civilization, and a very important one; it furnishes a field in which epoch-making discoveries have been and will be made. To the young man in search of a profession there can hardly be a domain that promises more in the way alike of achievement and of return; and in his present article Mr. Yates tries to show just what pursuit of this promise is likely to yield.*—THE EDITOR.

### An Embargo on Fossils

AMERICAN savants, who have been excavating prehistoric remains from the wonderful valley of the Red Deer River in Alberta, Canada, which is held to be the Grand Canyon of Canada, may not be privileged much longer to take away these remains without let or hindrance. A very active campaign is under way in Alberta to have measures taken to place the removal of the fossils under restrictions to the end that the best of the remaining specimens may be kept for Canada.

For the last twenty years scientists from the United States have been digging out the fossilized skeletons of the monsters of the bygone ages. They have not been interfered with in any way and have had the full privilege of shipping out such specimens as appealed to them. Hence in New York, Washington and other places are to be found amazing skeletons built up from the fossilized bones gathered in this province.

On the other hand, the Dominion of Canada has no such specimens and the complaint is made that the youth of this country are debarred from seeing the rebuilt animals that once roamed the prairies. The defense of the government officials, who have not previously imposed any barriers to the export of the specimens, is that there are enough prehistoric remains, in the shape of fossilized skeletons, in the Red Deer Valley, to supply the museums of the whole world and leave countless numbers over.

# Do Fish Swim as Airplanes Fly?

## Striking Analogies Between the Laws Governing These Widely Divergent Styles of Moving

By M. Tevis

INVESTIGATORS have often attempted to find some parallel in the animal world to the motions made by the propellers of vessels and aircraft. So far as we know, however, there is no case exactly parallel, i.e., no active rotation of a portion of the body comparable to that of a propeller in any animal outside the protozoa. An analogous motion, however, to that of the propeller is that of a fish in water, as has been recently demonstrated by a German professor, Dr. Richard Hesse of Bonn. Just as the motion of an airplane or a dirigible depends upon the creation of air resistance, the swimming of a fish depends upon the creation of water resistance. The laws governing the motion of bodies in water and in air are of like nature. In both cases the moving body receives a buoyant impulse, i.e., it loses as much weight as is equal to the weight of the mass of water or air which is replaced; but since water weighs 760 times as much as air it is, of course, 760 times as buoyant. In each of them the resistance which a moving surface encounters increases in the same proportion as the area of the surface; but it increases according to the square of the velocity with which the surface moves.

Since the particles of air are so much more readily pushed out of place than those of water, much greater velocity is required in the air to produce sufficient resistance to support a given load. On the other hand the air offers correspondingly less resistance to the forward motion of the moving body and thus permits the attainment of much higher velocities. An interesting illustration of this fact is suggested by Dr. Hesse. Even such a powerful swimmer as the salmon moves on an average only at the rate of 0.8 meter per second, whereas a bee travels 7 meters in the same length of time, a pigeon 19 meters and an airplane as much as 39 meters.

A bird flies by means of a series of rhythmically repeated impulses at an irregular rate of speed. The motion of a fish, on the other hand, approximates that of a screw revolving in water or in air. By means of the revolution of the propeller a surface (the slanting plane of the thread of the screw) is driven constantly forward in the direction of the axis of the latter. When the propeller is revolving in water these surfaces move forward like oars and meet with the resistance of the water which drives them in the opposite direction.

In the same manner serpentine movements of a wave-like form traverse the body of the fish from head to tail. Each of these serpentine waves compresses the water in front of it like the blade of an oar whose height depends upon that of the body of the fish and whose breadth is equal to the amplitude of the serpentine wave. In the case of the eel, in which the height of this pseudo-oar-blade is small, the breadth must be correspondingly greater. In the carp, on the contrary the height is greater and the breadth correspondingly less; in the case of the carp, however, the effect is heightened through the fact that the waves progress with greater rapidity, the resistance being thus increased according to the square of the velocity.

Still another interesting comparison is made by Dr. Hesse between the swimming of the fish and the progress of human aircraft. Just as some of the latter are heavier and others lighter than air, so we have fish that are heavier than water and others in which the weight of the displaced mass of water is equal to that of the body, just as a lighter-than-air balloon becomes of equal weight with the surrounding air at a given altitude. The former are those fish which have no swimming bladders and especially the sharks; while the latter include all those numerous fish which obtain equilibrium by means of their air-filled floats or swimming bladders. And just as dirigibles and airplanes differ in their motion so do these two classes of fish—thus we see a gold fish in a glass aquarium floating about like a balloon, whereas a codfish sinks to the ground like an airplane when he is not moving. Furthermore, those fish supplied with swimming bladders can swim as slowly as they please, whereas a shark must maintain a definite minimum of velocity in order that his forward motion shall create sufficient resistance of the water against his underside to balance his excess of weight.

It may be observed, too, that the fish having no swimming bladders have need of special supporting surfaces in order to afford the resistance of the water a suitable point of attack; and the slower their motion the larger these surfaces must be. It will be generally found among such fish that the ventral surface is broad and flattened, rising in a sharp angle toward the point of the snout in the case of fish which swim horizontally. The fins, especially the breast fins, serve to enlarge this under surface and are, therefore, much larger than in most fish which possess swimming bladders; and are likewise much more strongly supported by portions of the bony structure.

In the case of fishes with swimming bladders the paired fins are usually employed for steering like the horizontal rudder or elevator employed to turn the airship upward or downward; and the form of the body is not subject to such limitations as in those fishes not so provided. Hence we find a great variety of forms among the former.

Another point of analogy is that just as airplanes are capable of attaining a higher velocity than dirigibles, so we find the greatest speed among the heavier-than-water fishes, *i.e.*, those without swimming bladders, examples of which are the shark and the mackerel. The muscular activity of some of these fishes for swimming is so great in fact that the internal temperature is no less than 10 degrees Centigrade higher than that of the surrounding water. When there is such a strong driving power a smaller under-surface is necessary in order to obtain the necessary buoyancy; on this account the mackerel's fins are small and capable of being pressed into grooves in the body of the fish, lessening the friction of the passage through the water.

Both sorts of fish are capable of a movement through the water which may be compared to that of volplaning. Fish provided with swimming bladders accomplish this by compressing their bladders by the action of powerful muscles, thus quickly achieving a comparative increase in weight. At the same time they spread their powerful breast fins in order to obtain a larger lower surface.

### The Greek Contribution to Good English

To the Editor of the SCIENTIFIC AMERICAN:

An editorial in your issue of September 11 holds up to mild ridicule certain formidable-appearing words of Greek parentage, and says of them and their brethren that they "shuffle along in the procession of our discourse as the limping, the lame and the halt in a gay parade, uncouth, incongruous."

It seems to me that this view of these useful words is somewhat like the objection to the steam shovel, that compared with the automobile it does not develop much speed. Take "schizophrenia," for instance, one of the words cited to the bar for contempt proceedings. It is not found in the edition of the Century dictionary that I own, and my medical dictionary is not by my side. Yet the little Greek I know tells me that it means a mind divided against itself—a form of insanity in which one's mentality does not coördinate. That word, and others like it, are by no means holiday paraders. They are the tools of a particular craft, never used by the flippant verbal merry-makers, but very useful to specialists. No one claims that logarithms are joy-riders; but to the surveyor in the woods, and to the skipper on the lonely ocean, they are as handy as a jack-plane to a carpenter; and to a boy who has studied Greek for a year such words as this are fairly phosphorescent in their illumination of his technical reading.

Now as to the general utility of Greek in the English language I offer in evidence the admirable article in the SCIENTIFIC AMERICAN of September 18, "New Concepts of the Past Century" by the Einstein prize essay editor. If we eliminate the Greek-derived words from that article, it can hardly be transplanted into Anglo Saxon speech. Let us see. The article says that "the classical geometer regarded his science as the study of observed phenomena, of space considered as an entity." Oh, you wise engineers and craftsmen who jeer at Latin and Greek, try to say in Anglo-Saxon English just what is meant by that sentence. The men of old England before the Norman Conquest knew about a lot of thinks like logs and dogs and hogs, but when it came to psychology and technique and characteristic phenomena, and things mathematical, analytical and philosophical, their geometry and their axioms and their postulates were missing.

We scarcely realize the influence of Greek words on our thought. Sympathy, aristocracy, eulogy, democracy, authority, character, pneumatic, kaleidoscopic, dynamic, physics, psychology—all the choruses of the choirs invisible—without the Greek our language would grovel and plod and get stuck in the mud. And the long words of the specialists, they hurt nobody who does not understand them. They wait patiently on the shelf till they are needed by someone who knows how to use them.

It is notorious that engineers and other able handlers of things tangible, when they try to explain what they mean in court and in public speech, stumble and fall down in a way that would put to shame a high school boy. When you find one who can express himself without pencil and paper and diagrams you almost invariably find him to be a man who has studied Latin and Greek, and thereby obtained a ground knowledge of his own complex mother tongue.

Washington, D. C. FRED IRLAND.

### The Round-Trip Paradox

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of September 4th, 1920, under the caption "Wanted—A Proverb," you speak of critics of the results of the Michelson-Morley experiments. Perhaps your simple-minded critics will understand the problem of the rower up and down stream by a change of venue, so to speak.

The twelve miles rowed is between stationary points, but the rowing distance is in a moving medium and the actual points of the journey are in the water. For instance, assume a moving sidewalk traveling at the rate of two miles per hour. A man walking four miles an hour, if he walks against the direction of movement, in six hours will have advanced twelve miles from the point of the stationary platform at which he stepped on to the moving walk; but he will have walked twenty-four miles from the point of the walk at which he stepped on to it. Now if he returns, he will in two hours walk eight miles back on the surface of the moving sidewalk, but as the walk travels two miles an hour, he will at the end of his two hours be able to step off at the identical point on the stationary platform at which he began his journey. In other words, his eight-hour walk has covered thirty-two miles of the moving walk's surface, twenty-four going and eight returning, and not merely twenty-four miles, twelve going and twelve returning, as would be the case if he walked on the stationary platform from one point to another twelve miles distant on the same platform and back.

Similarly, the rower is actually traveling twenty-four miles' distance on the surface of the moving stream going and eight returning. If instead the rower traveled twelve miles on the surface of the stream each way, he would pass between two points on the bank six miles apart going, and returning would pass between the upper point and a second point downstream on the bank eighteen miles apart. Thus, in six hours he would actually traverse twenty-four miles on the surface of the stream and pass by twenty-four miles on the bank, but the two legs of his journey in the stream would be equal, twelve miles each, while the two legs of the bank passed by would be unequal, six miles and eighteen miles. To make the two legs of the bank passed by equal, twelve miles each, he has to make the two legs of his journey in the stream unequal, twenty-four miles and eight miles, the total of which, being thirty-two, is greater than in the former case, and therefore requires two hours more time. I think many people will find this the simpler explanation of the apparent paradox. R. H. FERRIS.

# Putting the San Joaquin to Work

## Some Details of the Water-Power Development in California's Fruitful Valley

By Arthur L. Dahl

CALIFORNIA has always been looked upon as one of those States peculiarly blessed by Nature, for the wonderful resources of this sunny land embrace not only the food products so luscious and popular, but extend to vast reservoirs of minerals and oils, extensive forests, and finally enormous quantities of undeveloped water power. Mountain ranges, like a huge backbone, run through the State from Siskiyou to San Diego, and the falling waters from these mountains are capable of developing 9,250,000 horse-power of which only about ten per cent, or 942,000 horse-power has been developed to date.

Oil is produced in many different districts of California, providing a convenient and cheap source of power for all industries, for the pipe lines from the oil districts extend for hundreds of miles, bringing the liquid fuel to the refineries located on tide water, where ship and locomotive can load easily. In spite of this abundance of oil fuel, the industrial development of the State has been so rapid that all of the hydroelectric power companies have been taxed to the utmost to meet the demands for electric power, particularly for agricultural use. California is said to use more electricity on the farms of her State than any other State in the Union, most of this power being devoted to pumping water from subterranean sources to irrigate the valleys.

It is commonly said of the West that the value of land depends upon the amount of water available to irrigate it, but in the San Joaquin Valley of California the people say that the value of land depends upon getting electric power to develop it. In Kern, Kings, Fresno and other central California counties are millions of acres of level, fertile land, dry and unproductive now, for lack of surface water, but capable of being turned into garden spots by the water pumped from the hidden reservoirs, and in the conversion of these desert lands into highly productive fruit and grain lands, electric power is playing a major rôle. An electric motor is the most satisfactory and ideal source of power for pumping water, for it need not be watched or attended, unlike the gasoline engine or other power plant. For this reason the development of the San Joaquin Valley is largely dependent upon hydro-electric power, as it has been estimated that less than 10 per cent of the agricultural possibilities of this region have been developed.

In the very heart of this vast region of potential possibilities is the San Joaquin Light & Power Company, which supplies electric power to a very wide district. At the close of the war this company had a maximum generating capacity of 63,000 kw. from nine hydro-electric plants and three steam plants, and this power was inadequate to the needs of the district. During the present year the company has completed a new 12,500 kw. addition to the natural gas-burning steam plant at Bakersfield, and in September, 1920, the new 30,000 kw. Kerckhoff hydro-electric plant on the San Joaquin River, 45 miles from Fresno, was put in operation. The company plans further development of its hydro-electric possibilities so that between 270,000 and 300,000 hp. will be made available in its Kings River project, at an estimated cost of over $50,000,000.

So urgent was the demand for power for pumping that the company had on file in excess of 600 applications for power which it could not supply, and the Kerckhoff development was pushed with all possible speed to increase the needed production. Work was carried on night and day, and a number of new schemes were put into effect to expedite the work. For instance, steam shovels were used to excavate the material in driving tunnels, the muck being carried away by a 5-ton electric motor pulling the dump cars.

The project consisted of building a dam 110 feet high across the San Joaquin River at a point about 4½ miles northwest of Auberry. At this point the entire waters of the San Joaquin river are diverted through a series of tunnels 17 feet wide and 17 feet high, a distance of 17,000 feet to the forebay, located about three miles due west of Auberry, from which point the water is carried through three steel penstocks 8 feet in diameter, tapering to 7 feet at the power house, where it operates three turbines of 16,000 horse-power capacity each.

While borings were being made at the dam site, work was likewise being carried on to construct the necessary roads through the mountains for the transportation of construction material, and a complete camp for housing the men was constructed at the dam site. To get the material from the end of the newly-built road to the dam site, high above, an electric hoist was installed and an incline tramway constructed. Two steel cableways were installed, having a 500-foot span, and a capacity of 20 tons each, and these cableways were used for transporting material from the incline railroad to the dam. On one side of the site an enormous body of gravel had to be removed before the concrete foundation could be laid, and a revolving steam shovel was taken across on the cableway and used in getting rid of this gravel, which was hauled across on the cable. When it came to lay the foun-

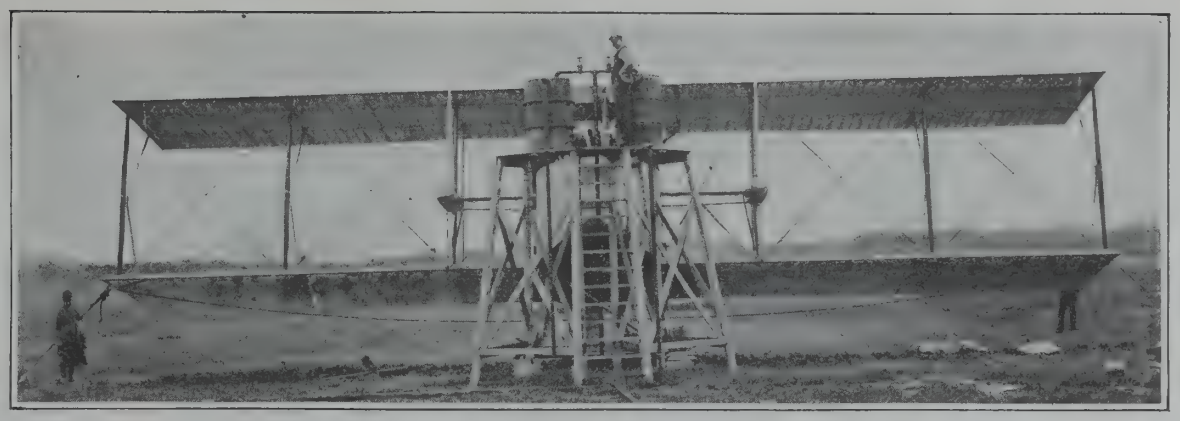
## Trans-Oceanic Airplane

### Multiple Engines and Transmission Gears as Aids to Continuous Flight

SEVERAL years ago when the development of the airplane was in its preliminary stages, Mr. Edwin Gould offered through the SCIENTIFIC AMERICAN a prize of $15,000 for a successful airplane driven by two or more engines, capable of being connected up or run separately at will. The object of this offer was to promote safety of travel by dividing the total engine power among several units in such a way that the failure of one unit would not necessitate an immediate landing or loss of control.



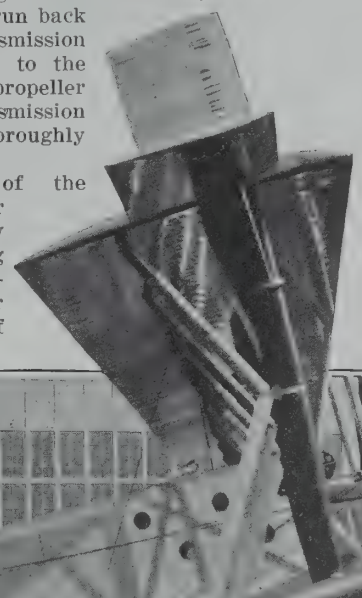
**The seven-ton Martin bomber under test by the U. S. Army. The engine speed is 2000 r.p.m., and the propeller speed 1000, yet no signs of vibration show in this photograph. Each engine may be disconnected at will from propeller shafting**

In the SCIENTIFIC AMERICAN of February 3, 1912, we published an article by Mr. James V. Martin, entitled "Can the Atlantic Ocean Be Crossed in an Airplane?" in which the writer discussed the possibilities of transatlantic flight and presented his design for a large hydro-airplane equipped with five Gnome engines connected up to two propellers, one on each side of the fuselage. The important feature of this design was the location of these engines in a single compartment at the front end of the fuselage, and the provision of clutches and a suitable transmission gear, which enabled any temporarily disabled unit to be disconnected while repairs were being made. In the intervening years, Mr. Martin has developed this system, and its latest application is shown in the accompanying photographs of what is known as the Martin seven-ton transmission bomber, which, it is needless to say, was developed for war purposes. The two photographs were taken on the army flying ground known as McCook Field, at Dayton, Ohio.

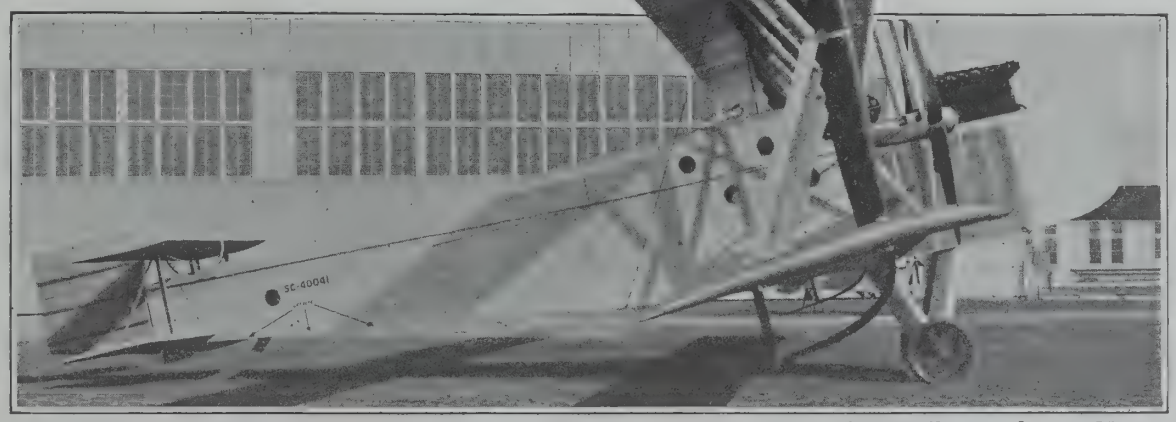
If the transatlantic airplane is ever to compete with the transatlantic steamship, it must be made absolutely safe and reliable. Passengers must go aboard the air liner with the same sense of security with which they board an "Aquitania" or an "Olympic." To secure these conditions, the promoter of airplane travel must find some way to make the motive power as dependable, even more dependable, than the motive power of the steamship. Everyone knows that it is far from being that at present, and the reason is not far to seek. It is found in the fact that if one or more of the engines goes dead, it must remain dead to the end of the voyage; for it is practically impossible to make the necessary adjustments or repairs when, as is now almost invariably the case, each engine is directly connected to its own propeller and is either placed in the open or enclosed in a shell or "egg" which is so contracted as to provide insufficient room for the mechanics.

The inventor of this machine believes, and we are inclined to agree with him, that the air liner of the future must be provided with a multiplicity of propellers connected up to a main transmission shaft, which is driven by a multiplicity of engines placed in a roomy engine compartment, each engine being independently clutch-connected to the transmission shaft, so that any engine that is in trouble can be thrown out of engagement, leaving the rest of the plant to "carry on" while repairs are being made.

The seven-ton machine which we illustrate is driven by two Liberty engines carried side by side in a closed compartment in the nose of the machine. In the accompanying side view, the hood of this compartment is removed, showing the starboard engine. When the machine is in flight and the hood in place, the mechanics find themselves in a closed engine room with fair head room and sufficient space around the engines to give them sufficient elbow room. The two crank shafts run back to a transverse transmission shaft which is geared to the inboard ends of the propeller shafts, the whole transmission being of strong and thoroughly stiff construction.



Our front view of the bomber shows the gear under test by the army at the McCook Flying Field. Because the machine was stationary for the fourteen hours of the test it was necessary to provide two tanks of cooling water which were carried on a platform, as shown. Of particular interest is the clear definition of this photograph, for it was taken when the two Liberty engines were being run at 2,000 revolutions per minute and the propellers at 1,000, and serves to demonstrate that a gear of this character, while transmitting a total of 910 horsepower at these high speeds can be so built and emplaced that the machine shall be practically free from vibration.



**The seven-ton Martin bomber, with two Liberty engines, and a speed of 110 miles per hour. Note K-bar truss and aero-dynamic controls at the wing tips**

#### Transmission

The transmission weighs only seven-tenths of a pound per horse-power transmitted, while the mechanical loss due to the use of the transmission is nine per cent. Both of these losses are more than canceled by the propeller and motor efficiency due to the gear ratio of the transmission, which is two to one. The particular transmission used in this machine was designed and built to carry only 625 horse-power; but in this test it stood the 900 horse-power developed by the two high-compression Liberty motors when running at 2,000 revolutions per minute. The static tests extended over fourteen hours, with continuous runs of four hours; and the entire absence of vibration, together with the perfect ease with which either motor could be engaged or disengaged at high speed by the operation of its clutch, proves that this type of transmission is ideal for the heavy duty, long-distance airplanes of the future.

#### Reduction Gear Effect

An interesting parallelism between airplane and steamship drive is seen in the fact that this transmission is the counterpart, so far as efficient results are concerned, of the reduction gear of the steamship, where efficiency calls for a much higher speed in the turbine than in the propeller. The same conditions prevail in a more moderate degree on the airplane, and the transmission as used on this machine renders it possible to run both motor and propellers at the best theoretical speed for efficiency. In the Martin bomber, should one of the engines become disabled, a clutch disengages it and the remaining engine continues to drive the plane at 74 miles an hour instead of 110. This, however, is a safe speed and permits the disabled motor to be repaired in the shelter of the cabin, after which it is started by a self-starter and then synchronized and reengaged with the line shaft.

Other features are the use of the retractable chassis and the K-bar truss and the aerodynamic control at the wing ends.

## How Bradford Sweeps Its Streets

IN many ways the city of Bradford, England, sets the styles as far as the efficient running of a municipality is concerned. Bradford has long solved the street transportation problem by trackless trolleys which are models of their kind. And now Bradford is sweeping its streets by means of little vehicles such as that shown in the accompanying illustrations.

There is nothing absolutely new in the gasoline-driven street sweeper. Many of our American cities boast of such machines. The Bradford street sweeper carries sufficient water for a fair run, and the dirt is swept off into the gutters instead of being picked up in a hopper as in some of our American machines. Nevertheless, the smaller machine would seem to have certain advantages of its own, such as lower first cost and lower operating costs, not to forget its ability to work in pretty tight places, if necessary.

**Front and rear views of a type of street sweeper employed in the streets of Bradford, England**

# The "Super-Destroyer"

## Some Facts Concerning the Origin and Development of the Flotilla Leader

By Hector C. Bywater

THE flotilla leader, which is a super-destroyer, is a new type of vessel developed during the recent war. These vessels are used to lead flotillas of destroyers into action. Being larger than destroyers they carry the essential facilities for a flotilla commander. They are better equipped for signaling and range-finding, carry a heavier battery, and a much more efficient radio equipment than a destroyer. They proved themselves to be very useful in the late war, and are now generally recognized as being required by modern organization for destroyer operations. Also, these larger vessels were found necessary for screening battle-cruisers, where the ability to maintain high speed in a seaway is a prime necessity.

**H. M. S. "Wallace," flotilla leader of "Scott" class; displacement 1,700 tons, making 37.7 knots at 45,500 horse-power. Armament: five 4.7-inch guns, six 21-inch torpedoes**

The foregoing admirable summary of the functions of the flotilla leader is contained in the recommendations made by the General Board of the United States Navy for the building program of 1921. Five vessels of this type were included in the Board's program, which, however, has not been accepted by Congress, with the result that, for the next few years the United States Navy will have to do without a type of fighting ship which is possessed and highly prized by the other navies of the world. The flotilla leader is really an old type revived under a new name. It is the modern descendant of the "divisional torpedo-boat" and the "torpedo-gunboat" built during the closing decades of the 19th century, types which, in their turn, had sprung from the sea-going torpedo-boat and eventually became merged in the destroyer. The credit of having invented the flotilla leader must go to Germany, who some forty-five years ago ordered the "Zieten," a fast "torpedo aviso," from the Thames Ironworks of London. Although but 975 tons in displacement and barely 200 feet in length, she had a speed of 16 knots, remarkable for those days, and carried a powerful armament of four 4.7-inch breech-loading guns, with submerged tubes at bow and stern for ejecting the "fish" torpedo. The success of the "Zieten" led other powers to experiment with vessels of this type, from which there grew a very numerous family. It was only in Germany, however, that the original function of the "Zieten" as a leader of torpedo boats was kept steadily in view, though lack of funds prevented that country from perpetuating the type.

In 1906 tactical maneuvers held in the North Sea convinced the British Admiralty that the system of using destroyers in large flotillas of twelve to twenty boats necessitated the building of special leaders, or flag boats, from which the commodore in command could control his flotilla just as an admiral handles a squadron or fleet of battleships from his flagship. Since the ordinary destroyer did not offer sufficient bridge room, living accommodations, and other facilities for the commodore and his staff, it was considered necessary to design a vessel of larger dimensions, fitted up as a miniature flagship, and possessing superior qualities of speed and armament. The pioneer vessel of this type was the "Swift," ordered from Cammell-Lairds of Birkenhead, in 1906. She displaced 1,825 tons, was 353 feet in length and 34½ feet broad, and was equipped with turbine machinery of 30,000 S.H.P. to produce the then phenomenal speed of 35 knots, which was at least five knots more than the best British destroyer of the period could make. The trials of this vessel, which was launched in 1907, were watched with keen interest, as few engineers believed she would ever make her contract speed. But the first runs over the measured mile confounded the skeptics, for the best run at full power gave a maximum velocity of 38.3 knots—a world's record which remained unbroken for ten years. Her boilers were exclusively oil-fired, and the success of this innovation encouraged the British Admiralty to embody the liquid fuel system in their later destroyers. But this drawback to the "Swift" was her inordinate cost—£280,500 ($1,402,500 at normal rate of exchange). For this sum three destroyers of ordinary type could be built, and consequently no further leaders were built until 1913, in which year the "Marksman" and "Lightfoot" were laid down. The "Swift" performed most valuable service during the war, and her dashing exploit in April, 1917, when, in company with the "Broke," she fell upon six German destroyers in the Dover Strait and routed them with heavy loss, will long be remembered. Shortly before that action her original armament of four 4-inch rapid-fire guns had been changed to one 6-inch and two 4-inch, so that she was a most formidable opponent for any destroyer. Various structural modifications have now brought her displacement up to 2,207 tons, but she is still good for 35 knots.

The value of the flotilla leader is evidenced by the fact that during the war period every naval belligerent, with the exception of the United States, built many vessels of this type. Great Britain added no less than 34 of them to her fleet; Germany laid down flotilla leaders of unprecedented size and power; and both Italy and Japan evolved some very striking designs. The new French naval program includes six 2,000-ton leaders, and the U. S. Navy Department is known to have prepared plans for vessels of the same type, though their construction has still to be authorized.

The accompanying table shows at a glance the principal features of representative flotilla leaders built, building, and projected for the world's navies.

It will be seen from the accompanying list that the German flotilla leaders easily surpassed their contemporaries in size and weight of armament. These twelve boats—"S-113-115," "V-116-118," "G-119-121," "B-122-124"—were designed to form an "Iron Division," primarily for the purpose of defending the "Heligoland Bight" against British raiders and mine-layers. They are of peculiar interest, illustrating as they do the radical change induced in the German conception of destroyer functions as the result of war experience. Before the war German naval officers attached minor importance to the gun armament of their torpedo craft. Logically enough, they insisted that the torpedo was the only weapon that counted in this type, and that every ton of available weight must be devoted to speed and torpedo tubes. It was not until a whole series of their boats had been sunk or badly mauled by the heavier gunfire of British destroyers that they departed from this rigid principle. All the German pre-war boats mounted 3.4-inch 22-pounder guns, which were soon replaced by the 4.1-inch 38-pounder with a semi-automatic breech-block, enabling a very high rate of fire to be maintained. Guns of this caliber were supplied to nearly all the boats built during the war, and proved superior in range and smashing power to the British 4-inch. But it cannot be said that the German destroyers ever took kindly to artillery duels, and to the end of the war they never used their guns to full advantage.

What the big super-leaders of the "V-116" class might have done can only be surmised, for none of them was commissioned in time to take an active part in the war. A great mystery has been made in Germany about these twelve boats and the details of them given in the above list have not previously been published. Five boats were completed in the spring of 1918 and ran their trials in the Baltic. Most of them exceeded the designed speed of 35 knots, but the great weight of armament and the immensely powerful machinery proved too much for the scantlings, and all five had to go into dockyard for extensive alterations, which were still incomplete at the date of the armistice. The four 5.9-inch guns were on high-angle mounts and could be used either for flat trajectory fire or against aircraft. The projectile weighed 101 pounds and contained an exceptionally powerful bursting charge, which would have proved most effective against such comparatively flimsy targets as destroyers. The torpedo armament was limited to four tubes, mounted in pairs amidships, but these fired the new 23.6-inch torpedo, which is the most powerful weapon of its kind in existence. Its warhead is charged with 616 pounds of T.N.T.—practically double the quantity of explosive carried in pre-war torpedoes—and it can travel a distance of 16,350 yards at a velocity of 28 knots. Since it would be impossible to manipulate torpedoes and tubes of this size by hand, the "V-116" and her sister boats had special motors for loading and training the tubes. They were also fitted with the latest appliances for controlling

## Golf Without a Caddy

**By Elmer A. Sperry**

GOLFERS are being made faster than caddies. Nature apparently has little to do with the former, while we are compelled to leave it very much in control of the latter. It is more and more difficult to get caddies and those who do get them find them of little account. Some seasoned golfers absolutely refuse to carry their own bag over the course. No matter how experienced they may be, they are probably far wiser than they know; there is a decidedly startling and quite unsuspected reason why caddiless golf is exhausting. An analysis of the underlying causes is of more than ordinary interest.

Everyone knows that he gets tired in toting his own golf bag, much more so than seems at all reasonable. An abundant reason for this fatigue is revealed, however, in the *dynamics* of the proposition, which involves elements heretofore neglected. Analysis reveals the fact that it isn't toting the bag that makes one tired; in fact, we are quite familiar with the energies that this factor involves. It probably requires, in the great economics of nature, about 30 watt-hours per ton-mile to cover this part of the work. This means, where a player averages 2½ miles an hour, 2½ times 30, or 75 watt-hours to be multiplied by the tonnage of the bag, which equals roughly 1/200. This equals 100/266 or for two hours a total of 200/266 watt hours, which, being interpreted, means about the power required to raise about one ton through the distance of one foot or about one foot-ton of energy. This may seem staggering, but it is quite an unimportant factor as compared with one other of much greater magnitude, and it is this latter which really saps the energy of the player, namely, picking up his bag and its constant repetition. This tires him far more than has been supposed, actually over 24 times as much as toting the bag.

In lifting, it isn't the bag that weighs, but the *man*. We have lost sight of the player's own weight which is involved in this process. Suppose the player's center of gravity is lowered 2 feet at each pick-up and raised again, and his weight is 150 pounds. He thus exerts 300 foot-pounds of energy in lifting his own weight regardless of any other factor. Again the muscular energy involved in lowering himself is understood very well and is about ¼ of the above amount, or 75 foot-pounds. Again another quantity occurs in the small amount of stooping and rising again in the act of lowering the bag to the ground before making his shot. No player drops his bag any great distance—the clubs are too valuable for this. This factor averages about 85 foot-pounds. He of course also lifts the bag itself, say 10 pounds, through three feet, giving 30 foot-pounds additional for this item. Let us now add these items and see what it amount to—300 plus 75 plus 85 plus 30 equals 490 foot-pounds. Now let us suppose the course is an average hard course and our average player requires 100 strokes to go around; he will use up no less than 49,000 foot-pounds of energy or the amazing effort of 24½ foot-tons—more if he is a tall man, again more if he weighs in excess of 150 pounds, and doubly more if he is both, as many men are. And this in only one round. No wonder the player feels himself "all in" in toting his own bag in the old way. Here is an enormous store of energy that should be conserved for the game itself instead of being utterly and uselessly wasted—and what a waste! The kind that causes exasperating delays upsetting one's own game, and what is most exasperating, often that of many others as well.

Practically all of these 24-odd foot-tons of energy per man per round can easily be saved by the simple expedient of an upstanding or stabilized bag. Put a spike in the bottom of your bag and drive it into the turf. Do anything rather than drop your sticks. Personally, I was appalled at the results of these simple calculations. Accurate information as to the real seat of a difficulty allows us to engineer around it, in fact, in this case to avoid it entirely. In my own case it is very gratifying to know the real reason for "that tired feeling" after caddiless golf and to find it not wholly due to advancing years after all. I am happy to say that I have experienced complete relief from the extra fatigue, finishing a round fresh and ready for more, by employing this simple device of the upstanding, stable bag.

In my case I have been able to accomplish this by a little attachment which I designed for my light "Sunday" bag. It weighs only a few ounces and can be readily attached or detached. This was made by my boys at the works, who seem to take extra pride in providing the boss with an energy-saving device. This

(*Continued on page 482*)

**Mr. Sperry's up-standing golf bag that saves the caddiless player 25 foot-tons of energy per round**

## Keeping in Step

**By Ralph Howard**

THE latest departure in synchronous motor application is the installation of a very small self-starting motor in a clock, where it is used, in connection with a high grade clock movement, to compare the speed of a synchronous generator with exact time, in order to give a continuous check on generator frequency. Since any change in the speed of the generator is reflected in the speed of this small motor, whereas the clock speed remains constant, the combination forms an accurate method of maintaining constant average frequency.

These small motors can also be used on the system in place of clock mechanisms to drive graphic recording instruments, demand meters and time switches. By the use of this motor the synchronization of records from graphic meters and demand meters will be made possible; something that has always been desirable, but somewhat difficult of accomplishment heretofore.

In practice, a master clock containing two movements, one electrical, and one pendulum-operated, is located near the switchboard. The face is equipped with two pointers, one black, the other gold, rotating independently about the same center, on a dial, called the operating dial. The black pointer is so geared to the pendulum clock, as to make one complete revolution every five minutes. The gold pointer is geared to the small synchronous motor, so that when the frequency is correct it will rotate at the same speed as the black hand. All that the operator has to do is to hold the two pointers together—he will then have a fixed relation maintained between standard time, and generator speed, or cycles and time. This can be done by adjusting the speed governors of the prime movers. The master clock does not obviate the use of a frequency meter, or indicator, since it will not show instantaneous fluctuations in speed. Moreover, by using a frequency indicator near the master clock, the latter may be used as a constant check on the accuracy of the former.

The little synchronous motor which is the vital part of the electric component of the clock is only 2⅛ by 2⅝ by 2 9/16 inches in size, and is wound for operation on a 110-volt circuit. It consumes less than 4 watts at 110 volts, 60 cycles, but can be made for any one of the standard commercial frequencies. It is self-starting under load, reaches synchronous speed in less than a second and holds speed as long as the current is uninterrupted. It is simple in construction, and since its gearing runs permanently immersed in oil it requires but little attention to keep it functioning properly for an indefinite period.

There have been developed two forms of master clock, known as the type "A" and type "B." The principal difference in operation of these two is that in the "B" type, both the motor and the clock mechanism act on the same index hand, through gearing, so that the synchronous motor tends to drive the hand in one direction, while the clock mechanism tends to drive it in the opposite direction.

If the rate of the clock and motor are the same the hand rests at zero on the scale, but if the speed of the motor varies the hand is moved slowly in a clockwise or counter clockwise direction according to whether the variation is a gain or loss in speed. In this way the clock is caused to indicate variations in average frequency. The "A" type is that first described, in which control of the two speeds comes from comparison of two hands.

The installation of these master clocks will not eliminate fluctuations which are dependent to some degree on load variations, speed governor response, or steam pressure — features of operation which are more or less constantly encountered; but it does insure the maintenance of a more uniform as well as correct average frequency.

# Sending Photographs Over Wires

## Details of the Belin System To Be Tried Between St. Louis and New York

By Austin C. Lescarboura

THE important happening in Shanghai is printed in the New York newspapers the following morning. Indeed, so remarkable is our news-gathering machinery of today that half the world knows precisely what the other half is doing by the telegraphed or cabled or via radio word. And in due course the first half receives photographs of the happening in the second half of the world, thus completing the account; for if there is one thing certain in modern journalism, it is that photographs tell a story incomparably better and more readily than the best word picture.

Now, then, were it possible to transmit the story and the photographs simultaneously, our news-gathering machinery would be nearly perfect. Many a fine photograph must needs be discarded for the reason that it arrives too late to be of interest to the readers of large metropolitan newspapers. There is a tremendous wastage in this direction, due to the weeks and even months which must elapse in transmission.

With the urgent need for a rapid means of transmitting photographs before us, we can turn to the efforts of M. Edouard Belin of Paris, France, with a greater sense of appreciation. M. Belin has been working on the problem of transmitting photographs over wires since 1907. After certain changes in his basic designs as well as constant refinement in all the details, he has finally achieved noteworthy results for his latest system. In fact, he has to his credit the transmission of photographs over telegraph lines between Paris and Lyons, Paris and Bordeaux, Paris and Nice, Paris and London, and Paris and Antwerp.

At present M. Belin and his assistants are in the United States for the purpose of demonstrating the telestereograph, as it is called, over long-distance lines. The first test is to be between St. Louis and New York, and is being conducted under the auspices of the *St. Louis Post-Dispatch* and the *New York World*. It may be that M. Belin will later attempt the transmission of photographs between New York and San Francisco; but at any rate, he has come to this country of vast distances in order to put his system to the acid test, so to speak.

The first attempts at telegraphic transmission of autographical texts go back to the work of Abbé Caselli in 1860 and the device known as the Pantelegraph Caselli. The first attempts at the transmission of photography are attributed to the German, Professor Korn of Munich, who made use of selenium but later on, in a modified system, returned to a scheme very similar to that of Caselli. In the case of M. Belin the selenium and other delicate elements have been replaced by more practical means. The transmission is simply a matter of preparing a bas relief of the photograph, and then tracing that bas-relief with a stylus connected to a telephone transmitter. The latter varies the current flowing over the telegraph or telephone line in accordance with the relative height of any point on the bas relief record at any given moment. At the receiving end this current variation is translated into various gradations of light in the manner described further on.

The first step, then, is to prepare the transmitting record or plate. A copper cylinder forms the base of the record, and its surface is coated with a 5 per cent shellac solution. Meanwhile a carbon print is made in the conventional photographic manner from the photographic negative to be transmitted, after which the print is wrapped face to face with the shellacked copper cylinder. The cylinder with the print is then placed in hot water, with the result that the gelatine of the print adheres to the cylinder in accordance with its own degree of blackness, while the unexposed gelatine is washed away with the paper. In this manner a coating of uneven thickness is formed on the cylinder, or a photograph in bas-relief.

**Reproduction from a photograph received by M. Belin's apparatus. Note that in our half-tone reproduction considerable detail is lost**

The copper cylinder is then placed in the transmitting device which bears a close resemblance to the cylinder type phonograph. As will be noted in the two illustrations of the same transmitter at the head of this account, the components of the transmitter are: *A*—A special microphone with a stylus *B*, which is in constant contact with the face of the cylinder. *C* is another form of stylus, about which we shall have more to say further on. *D* is a speed regulator, controlling the clockwork which drives the transmitter. *E* is the copper cylinder with the photograph in bas-relief. The cylinder, it will be noted, can be inserted or removed with as much ease as the changing of cylinder records on the phonograph. *F* is a two-speed gear transmission, driving the cylinder. *G* is the synchronizer, which causes the receiver to keep in step with the transmitter by a series of electrical impulses sent over the line.

As the copper cylinder revolves, the microphone, with its stylus always in contact with the record face, is slowly moved along the record, touching practically every part of its surface. As the unevenness of the surface depresses the microphone stylus more or less, the current flowing through the microphone is modulated so as to correspond with the varying density of the photograph.

The receiving end must translate these electrical variations back into the original photographic terms. This it does in the manner indicated in the line drawing which forms the insert of the two illustrations at the head of this account. First of all, we have a special form of diminutive arc light shown at *L*, which sends its rays through the condenser *C* and the aperture *A* and again through the lens *B* on to a tiny mirror *M*. The mirror is mounted on the twin wires of a Blondel oscillograph—an apparatus with powerful electro-magnets and a pair of silver wires which carry the oscillating mirror, located in the powerful magnetic field. The Blondel oscillograph is a highly sensitive apparatus, and the immersion of the wires in thick oil causes the action to be practically "dead beat," or, to put it in another way, the wires have little momentum. As the current of varying intensity comes over the wires to the receiving set, the wires of the Blondel oscillograph cause the tiny mirror to turn more or less on its axis. However, no matter how far the mirror may turn, its reflected beam still passes through the screen *S*, the lens *C*, the almost microscopic aperture at *T* and on to the sensitized surface on the cylinder *D*.

The whole crux of this apparatus is the screen *S*, which is a screen of varying transparency. That is to

(*Continued on page 483*)

## From Coal Barge to Ship's Bunker

A COAL barge with an elevator and chute has made its appearance in San Francisco Bay and has as a purpose the direct coaling of a ship while the cargo is being unloaded, obviating the necessity of the ship's proceeding to a bunker wharf to receive its fuel. Instead of the usual clam-shell bucket, such as is used at bunker wharves, the coal is sent up on an elevator and slides down a chute into the ship. A donkey engine on board operates the elevator.

**This coal barge delivers its coal directly to the ship by means of an elevator and chute**

## Converting Steel Back Into Iron

CONSIDERABLE has been said and written about making steel in the electric furnace, which is a development of the last four years. Not so much has been promulgated about making pig iron from steel in such a furnace. It is standard practice to make pig iron, from which all steel is originally made, by smelting iron ore in a blast furnace and thus reducing or converting it to metallic iron, so-called, in the shape of pig iron.

A new and unique method has recently been developed however for converting scrap or old steel *back* into pig iron. Why this is done or even is necessary needs explanation first. At times certain kinds of pig iron are hard to obtain as made by standard methods. This has been true lately in Canada and France. It was therefore necessary to make it by a new method if possible.

The illustration shows how this was and is done in France. It represents a French electric furnace for converting scrap steel back into pig iron, something never thought possible nor probable only two or three years ago. Scrap steel or borings or turnings are charged from the upper flat form into the top of the furnace shown. Electricity is conducted into this furnace by the apparatus suspended from the wall. When the crude steel is melted certain additions are made to it so as to increase the percentage of carbon, silicon, etc., and very soon after the mass is tapped out at the bottom, as shown, in the shape of pig iron. It can be seen flowing into systematic molds made in a bed of sand. When cold it is removed and is called "pig" iron because each section of iron is attached to the central larger section or trough much as pigs gain their sustenance from the mother sow.

Many tons of such iron has been made in both France and Canada and it is regarded as, or can be made, the finest pig iron of any.

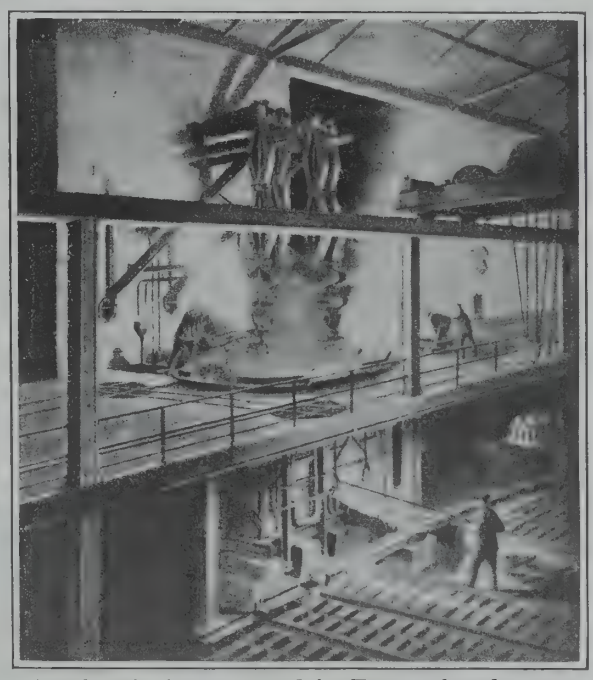
## The Motorcycle's Future

NOW that the former British and German motorcar owner has to be content with the more modest motorcycle, we may look for a considerable development along the lines of general utility and cheapness, says a writer in a British technical review.

Before the war the tendency of the motorcycle, under American influence, was towards increased weight and horse-power, and consequent complexity. Now, however, the chief considerations are safety, lightness, and simplicity to meet the requirements of the average man, who wants a cycle that will start up without causing him undue exertion, that can be lifted up and down steps and is not prohibitive in price or upkeep.

The lines on which improvements should proceed are, above all, toward simplification and comfort. The belt drive, a fruitful cause of breakdown, must be eliminated, the various parts simplified and their number reduced, the lighting system should be made as elementary as possible, and all complicated control on the handle-bars suppressed. Special care must be given to the brakes and the saddle should be made adjustable to the rider's comfort.

Another paramount necessity is that wheels should be made easily removable, in view of rendering the repair of punctured tires as simple a matter as possible, and there is plenty of scope for improvement in the tires themselves. High speed is not required, therefore the engine can and should be as light as is compatible with reliability. The development of the motorcycle as the plain man's vehicle also promises a future for the autowheel and motorscooter.



**An electric furnace used in France for the purpose of converting scrap steel back into pig iron**

## Shall We Wear Paper Clothes?

BEFORE we part with a good share of our yearly income for a serge or woolen suit, it may be a matter of real wisdom to look into the paper clothes situation. At any rate, the Bureau of Foreign and Domestic Commerce has on exhibition a large assortment of Austrian paper clothing and associated paper articles collected for the information of the American clothing and other interested industries. The exhibit includes workmen's suits, table covers, collar and cuffs, laundry bag, wall decoration, twine and other articles.

In this interesting collection there is a suit made of 40 per cent paper, which sells in Austria for 575 crowns, or about $2.65 in American money at the present rate of exchange. A workman's all-paper suit in brown is quoted at 32 crowns, or about 15 cents in American money. A blue all-paper suit is more expensive, 120 crowns (about 55 cents) being the asking price.

The report which accompanies the paper samples states that the garments are really washable, cold water, soap, and a scrubbing brush being the proper means. It is also reported that during the past year Austrian paper goods manufacturers have exported large quantities of their output to Italy and to Turkey. A previous report spoke of about 40,000 German paper suits being on display in a store on the Strand, London. After a brief stay in the Bureau of Foreign and Domestic Commerce, the paper articles will be offered to clothing and other interested manufacturers for examination.

## A Grass Lawn Like a Carpet

IT is proverbially a slow business getting a good grass lawn in a garden, but a new English idea makes it possible to secure a fine stretch of verdure just as one would buy a carpet at the stores. Grass seed is sown thickly on strong canvas and, when this is thickly covered with growth it is ready for making the lawn. The site is well prepared, being made perfectly level and special attention is given to getting the soil so that it is a favorable rooting medium for the little plants. Then the grass mats are put down on sections, these being closely fitted together. As time goes on the roots push down through the canvas and, in this way, establish a permanent lawn. Ultimately the material will rot. The value of this plan lies in the fact that an immediate effect can be secured. It is quite easy to have a splendid grass lawn in a situation where, a few hours before, there was nothing of the kind. From thenceforward the grass will go on improving and the little plants speedily take a hold on the soil.

## A New Kind of Coal

HERE is a new suggestion as to fuel—a new kind of coal. It is especially timely with coal at the high prices at present obtaining. The idea comes from Norway and is the result of experiments carried out in a plant at Greaker, Norway, where an improved process has been employed to produce sulfite coal as a by-product from the manufacture of wood pulp.

A ton of wood pulp yields 9 to 10 cubic meters of sulfite lye, of which 95 per cent is available for the production of coal, compared with about 60 per cent from other processes. If the new process is generally adopted it is estimated that it will be possible to produce annually sulfite coal equivalent to 800,000 tons of imported coal.

Considerable quantities of cheap alcohol are produced from the wood pulp lye before it is made into coal. An essential feature of the new process is high concentration of the lye before removal from the autoclaves. By concentrating it to 30 per cent not only is a high percentage of coal-producing substance obtained, but the quantity of solid matter is increased by 50 and even 70 per cent.

## A Fountain for the Cows

THE average dairy cow drinks anywhere from 60 to 100 pounds or more of water daily—in fact unless she gets plenty to drink, her milk yield will be visibly reduced. That is why dairy farmers devote particular attention to equipping their farms with all the modern facilities—somewhat in the nature of dairy cow soda fountains—for satisfying Bossie's thirst.

One eastern farm has provided durable concrete water tanks in each field where the cows are pastured. The tanks are connected directly with the farm water supply, a float being placed in each tank so that the water level is maintained at the same point all the time. Considerable trouble obtained due to the fact that the cows would nose and damage the floats so that they would not work properly. Then the owner devised the type of tank shown in the accompanying picture which provides a sort of square-shaped nub at one side of the tank for the float and the inlet and overflow pipes. An iron framework is provided over the top of the compartment so that the cows cannot reach or touch the float with their noses. Now Bossie and her mates never lack for fresh water as the dairy never runs dry.

**This concrete fountain serves fresh water to a herd of cows without attention of any kind**

**This side car can be attached or detached in a few minutes and adds little to the weight of bicycle**

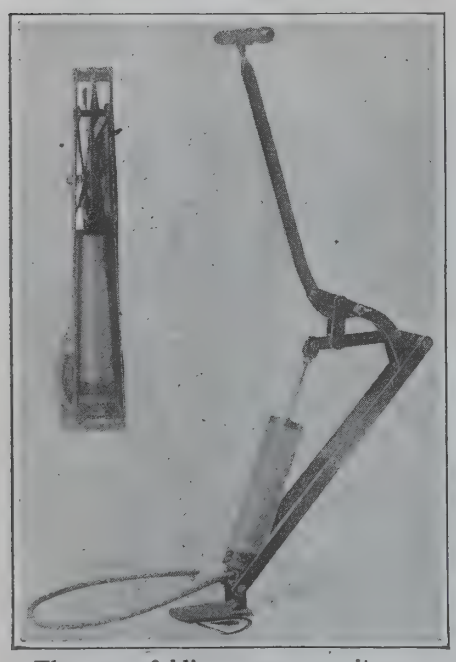
## The Bicycle with the Side-Car

THE bicycle is by no means obsolete in most European countries. Indeed, the shortage of gasoline and the economic situation as a whole have caused the European to hold on to his bicycle or even to go back to such a vehicle, while his more progressive and more fortunately situated American brother has gone on to automobiles, motorcycles, cyclecars, scooters and whatnot.

A recent European development is the side-car for bicycles, as represented by the accompanying illustration. Here is a side-car especially suited to the man who wishes to take along his child. The passenger may be up to seven years of age. The body has two large springs and ensures comfort in riding. It is provided with a windshield and a top. The body, which can be quickly attached or detached from the bicycle, adds very little weight to the latter.

## A Folding Air Pump for the Motorist

AN air pump which folds up into a small space and can be slipped into any tool box has been introduced by an Illinois manufacturer. The pump is operated on the leverage principle and it is claimed that it will force air against a pressure of over 250 pounds. Increased power and increased leverage are developed with each stroke. It is constructed of pressed steel and has no stuffing box. The only parts present in the compression chamber are a steel plunger with a heavy cup leather. Although the cylinder is quite short it is claimed that the friction is nominal and the pump has no tendency to heat. A 30 x 3 tire may be inflated to 60 pounds pressure in 60 strokes.



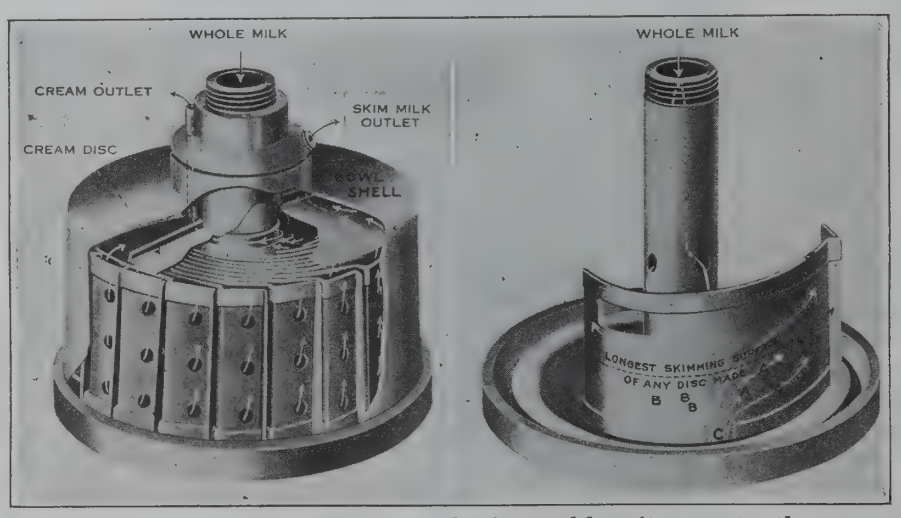
**The new folding pump as it appears complete folded and ready for use**

## Something New in Cream Separators

THE separation of cream (butter-fat) from the whole milk is due to the fact that the milk particles, being heavier in weight than the butter-fat particles, are thrown outward by the terrific centrifugal force exerted by the revolving of the bowl anywhere from 9,000 to 15,000 turns per minute.

Heretofore all disks in cream separators have been of the cone-shape design. The whole milk, flowing in at the top, has had to travel downward, between these numerous disks placed but ⅛-inch or less apart. Naturally, with this extreme velocity, and due also to the fact that both milk and butter-fat particles enter at the extreme edge of the disks, not all of the butter-fat particles can get out of the way, or, in other words, back up against this tremendous pressure, and are therefore carried along and out into the "skim-milk." This causes quite a loss of cream.

But there is now on the market what is known as the "straight disk"; the whole milk flowing first to the bottom and then entering each disk at its center, which, as shown in one of our drawings, gives the butter-fat particles *B* a chance to slip back toward the cream outlet, and out of the way of the heavier milk particles *A*, thus producing a separation that is practically 100 per cent.



**Details of the new cream separator mechanism and how it separates the cream from the milk**

## Revival of the Merchant Marine

DURING September, for the first month since the armistice, according to returns of the Bureau of Navigation, Department of Commerce, the increase in the American seagoing merchant marine owned by American shipowners has equaled and exceeded the increase in the Government-owned ships. At the last session Congress in the appropriation bills changed the war policy and directed the Shipping Board to maintain itself by sales of ships and shore property without further appropriations. During September the fleet of seagoing ships of 500 gross tons or over of American shipowners rose to 1,829, of, 4,625,324 gross tons, an increase during the month of 25 ships of 116,335 gross tons, while the Government-owned tonnage during the month increased only 20 ships of 88,855 gross tons, giving a Shipping Board total of 1,698 ships, of 7,288,208 gross tons, on October 1. Since January 1, 1920, however, the Government-owned tonnage has increased by 233 ships, of 1,347,466 gross tons, while the commercial marine of American shipowners has increased only 129 ships, of 536,926 gross tons.

## A Machine that Refinishes Floors

KEEPING any large dancing floor in first class shape is no small job, especially in the usual manual way. It has remained for inventors to produce a floor-scraping machine of the type shown in the accompanying illustration, which, driven by a powerful electric motor, travels over the floor, shaves off the old surface and smooths the new one, and then sweeps up all the shavings and dust into a bag at the rear of the machine. This machine makes the job of keeping floors in good shape relatively simple and inexpensive, particularly in these days of high labor costs.

## A Poison-Gas Gun for the Law-Abiding Citizen

THE good citizens of Paris seem to have taken the initiative in the war on criminals which must be fought in order to suppress the tidal wave of crime that has swept almost all countries since the termination of hostilities and the disbandment of large armies. It has remained for some ingenious Frenchman to produce a liquid poison-gas pistol, which is shown in the accompanying illustration.

This little instrument of protection for the law-abiding citizen has been inspired by the war. It has the advantage of putting an adversary *hors de combat* immediately, but without evil effects of any kind. The gun contains liquid poisonous gas which, if it strikes the bandit, puts him to sleep at once. Again, if it strikes the bandit in the eyes it blinds him for several days.

The handle of the gun contains the liquid poison which is compressed with the aid of a bicycle pump at the lower end of the handle. All one has to do is to point the gun at the target at a distance of not more than ten feet, and press the trigger which releases a thin stream which is accurate at that range. The liquid, emitting poisonous gases, disarms the bandit.

## Recent Patent Decisions

**Phonograph Horns.**—This case involves a patent of a horn for phonographs, the body portion of which is composed of longitudinally arranged strips of metal provided at their edges with outwardly directed flanges whereby said strips are connected, and whereby the body portion of the horn is provided on the outside thereof with longitudinally arranged ribs, said strips being tapered from one end of said horn to the other.

The complainant in this suit seeks to restrain the defendant from making, using, or selling phonograph horns infringing its patent issued to Peter C. Nielsen. It further seeks the profit realized by the defendant, and damages. The defendant denies liability on the ground that it did not infringe under any permissible interpretation of the patent, that the claims of the patent, if not wholly invalid, are entitled to a narrow construction only by reason of prior art patents and publications and prior state of the unpatented art.

Held that the Nielsen patent is valid. A patent for a device which performs a novel and useful function, as the horn in question for phonographs which did

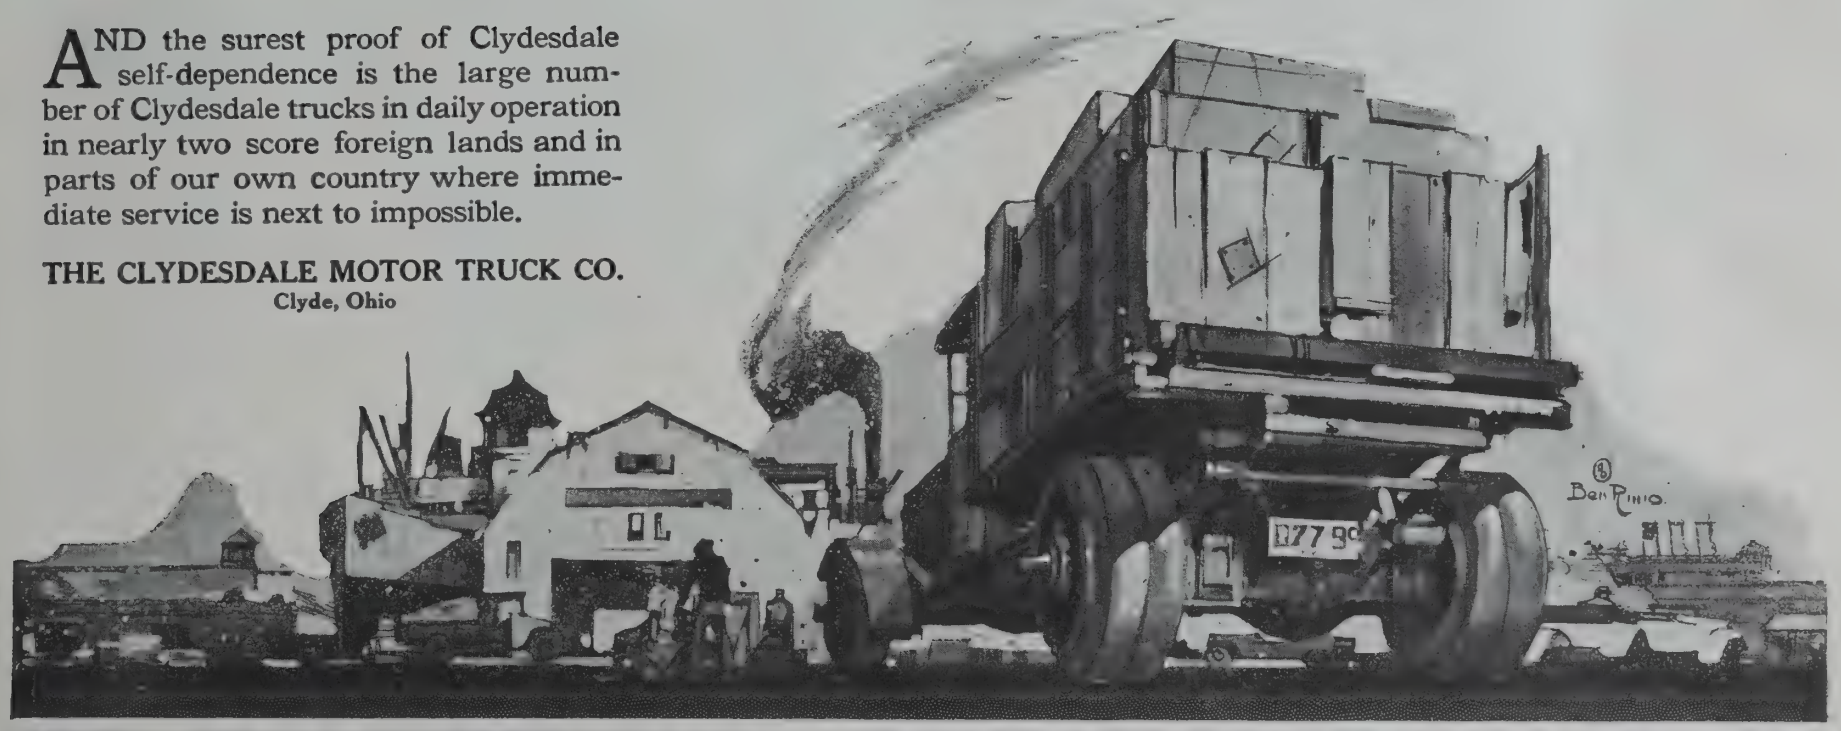
# DEPENDABILITY

## ONE TRUCK ON THE ROAD IS WORTH TWO IN THE SHOP

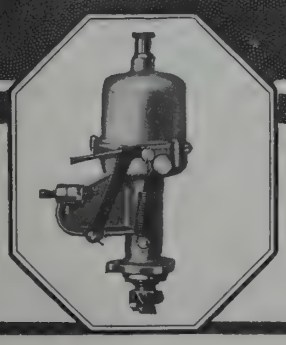
THE motor truck is only profitable if it is kept moving. To keep on the road and out of the shop, a truck must meet two important conditions: it must first be dependable in itself, and then it must be properly serviced. Dependability is paramount, though, for sometimes a truck must operate where service is not always instantly available.

AND the surest proof of Clydesdale self-dependence is the large number of Clydesdale trucks in daily operation in nearly two score foreign lands and in parts of our own country where immediate service is next to impossible.

THE CLYDESDALE MOTOR TRUCK CO.
Clyde, Ohio



# CLYDESDALE MOTOR TRUCKS



### An Added Feature of Dependability

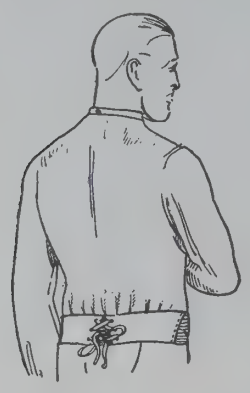
The Clydesdale Controller makes this truck reliable because it insures positive action under all conditions. By regulating the motor speed to accomplish just what is necessary, no more or no less, this automatic device prevents truck abuse.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Pertaining to Apparel

SHIRT.—J. P. MULLANE, 17 Ellsworth Ave., Cambridge, Mass. Among the objects of the invention is to provide a shirt which is practically tailless and which in lieu of the ordinary



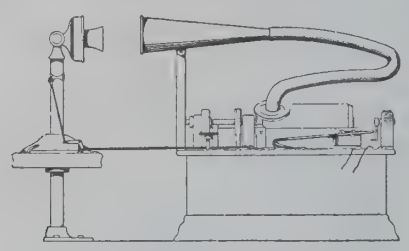
A REAR VIEW OF THE SHIRT IN USE

tails is provided with a belt which forms a part of the shirt and which fits snugly around the hips; the shirt is also provided with ventilated inserts below the arms which increase the wearing qualities, and add to the comfort of the wearer.

SLIPPER.—M. GAETO, 429 E. 127th St., New York, N. Y. This invention more particularly relates to a sole and heel construction which are adapted to be sold in combined form and have any desired upper or vamp attached. A further object is to provide slippers especially designed as bedroom slippers and the like and which will be strong and durable and easily assembled by any one of average intelligence.

## Electrical Devices

AUTOMATIC BURGLAR ALARM.—F. A. TERRY, Marshfield, Ala. The invention relates to burglar alarms comprising a telephone set and a phonograph disposed near the set, with brake mechanism for holding a switch hook



A SIDE VIEW OF THE DEVICE

in normal position, a motor, an electric circuit for operating the motor, and completing the talking circuit. An object is to provide an alarm which will send in a call for help over a telephone whenever put into operation by the opening of a window or door.

## Of Interest to Farmers

TAPPED WHEEL FOR PLANTERS.—C. L. HEATH, 2432 Cullom Ave., Chicago, Ill. The features of this invention are to provide a practical manner of actuating the seed dropping mechanism for check row corn planters which will do away with clutches, spring tension devices, friction devices, and other complicated means for effecting the desired result. This check row device may be conveniently applied to various makes of planters without materially departing from their original construction.

## Of General Interest

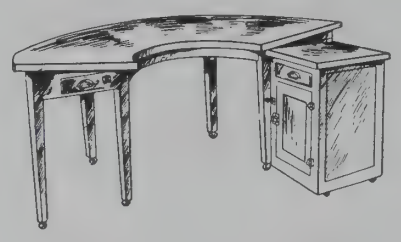
PENCIL.—H. L. BLACKMAN, c/o Parker Pen Co., Janesville, Wis. The invention pertains more particularly to that type of pencil in which a lead is fed longitudinally of the body of the pencil. It is the prime object of the invention to provide a novel form of lead-feeding mechanism and lead holder, and further to construct a pencil of this type which has the fewest number of working parts.

DEVICE FOR CONSERVING CORD AND TWINE.—O. A. GALE, Eaton, Ohio. The invention relates to means for conserving cord of odd lengths, especially in connection with post office and like work. An object is to provide a movable rack which has a plurality of spring clips, into which odd lengths of cord or twine may be sprung temporarily so that they may be within reach for reuse, thereby avoiding the waste of much material.

GAS SCREEN.—T. A. BROOKS, Newton, Kan. The object of the invention is to provide a device adapted for use in connection with gas burners, for spreading and intensifying the flame. The screen may be used on any kind of stove in the ordinary manner except when gas pressure is extremely low. Then the vessel can be placed on the lugs of the screen.

SPOOL.—A. H. SCHLOERB, 94 W. 104th St., New York, N. Y. The invention relates to spools or winding cores upon which silk thread, yarn or other products of thread manufacturers may be wound or spun. It is an object to provide a simplified form of spool construction of paper or other very light weight material which will be cheap to manufacture and which will enable the thread manufacturer to inexpensively place silk thread upon the market.

BOOKKEEPER'S WORK TABLE.—B. P. BEESON, 23 So. Park St., Box 185, Sapulpa, Okla. The object of the invention is to provide means whereby accountants and book-



A PERSPECTIVE VIEW OF THE INVENTION AS IN USE

keepers can have their books within convenient reach without leaving their seat. Another object is to provide a device wherein the various books can be kept convenient for use, and in which the books can be stored and then transferred to a safe or vault.

POWER-OPERATED RAZOR.—W. A. FUSCH, 129 Merchant St., Decatur, Ill. Among the objects of the invention are to provide a razor which will simplify and shorten the usual process of shaving which will dispense with the necessity of lathering the face, which will not require the usual keen cutting edge, which is self-sharpening to a considerable extent, and which will cut the hairs in proper and close manner without injury to the skin, and will leave the skin in a healthy condition.

COURSE FINDER.—C. N. WESTWOOD, 1015 Princess Ave., Victoria, B. C., Canada. The invention has for its object to provide an instrument by means of which courses may be easily found and corrected. The device comprises a blade, a mariner's compass card mounted to rotate on the blade, a fixed indicator on the blade coöperating with the compass card, and an arc-shaped bar adjustable transversely of the blade and carrying indicators at its ends coöperating with the card.

MEANS EMPLOYED IN PRODUCTION AND MATERIAL CONTROL SYSTEM.—E. H. BICKLEY, c/o Bickley Mfg. Co., 1033 Chestnut St., Philadelphia, Pa. This invention relates to a chart for use in connection with a system for the control of production and material in a factory, although not necessarily limited to this use as it can be applicable to wholesale houses or other mercantile requirements. The system is so flexible that it will control and can easily be adapted to any kind of factory, regardless of the nature of the product.

FLASH LIGHT BAG.—G. A. LEY, 1627 Carmen Ave., Chicago, Ill. The invention relates to photographic apparatus. An object is to provide a flash bag including a supporting staff running from the crown of the bag to the lower ends of the bottom ribs inside of the bag, thereby keeping the flash which is created in the flash pan supported by the staff, a safe distance from the bag. A further object is to provide means for employing the smoke by a flap falling back automatically to uncover an opening when the bag is turned over.

FIRE FIGHTING APPARATUS. — J. C. WITT, 300 Main St., Pine Bluff, Ark. An object of the invention is to provide a portable and collapsible fire shield to be used adjunctively with the usual fire fighting apparatus, the shield being controlled in its erection and collapse by the telescopic action of the truck upon which it is mounted. Another object is to provide fire curtains at the sides of the supporting truck, with engine driven gear connections controlled by the operator, for raising and lowering the curtains to protect the working parts beneath the truck.

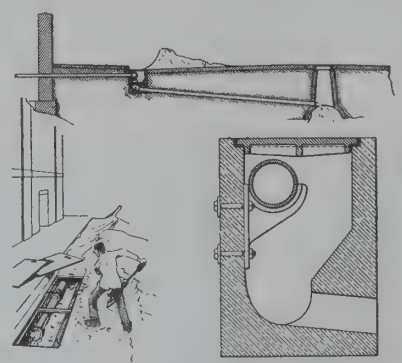
## Hardware and Tools

PACKING AUGER.—O. R. HYLAND, Box 680, Astoria, Ore. The object of this invention is to provide an auger especially adapted for packing comminuted substances in bags, as, for instance, flour and the like, wherein the arrangement is such that when the bag is filled with the required weight the vanes of the auger will be automatically thrown out of packing position into a position to check the further flow of matter to be packed.

## Heating and Lighting

FURNACE GRATE.—M. T. DAVIS, JR., Box 1244, Charleston, W. Va. An object of the invention is to provide a sectional grate for furnaces, provision being made in each of the sections for the circulation of water so that the heating area of the furnace is greatly increased. The sections consist of vertical hollow rear branches, and forwardly and upwardly inclining bottom branches, nipples securing the various sections together and affording water communication there between.

SNOW REMOVAL AND STEAM HEATING SYSTEM.—W. F. GUERIN, 1914 69th St., Brooklyn, N. Y. This invention relates to means for the removal of snow and has reference more particularly to a snow removal and steam heating system, which includes a steam



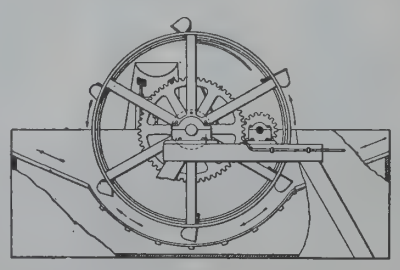
SHOWING THE ARRANGEMENT OF THE SYSTEM WITH RESPECT TO A STREET

pipe located adjacent the points where the snow accumulates, the steam pipes being adapted to melt the snow and cause the resulting water to flow away. An object is to provide means for quickly freeing streets and side walks of heavy snow falls.

## Machines and Mechanical Devices

ROAD SCRAPER.—C. M. DICUS, Gaffney, S. C. This invention relates to road scrapers of the type suitable for use upon country roads and of such form that it may be readily operated at a comparatively low cost. The scraper is a comparatively simple machine and can be pulled by horses or by a gasoline tractor and can be operated by one man.

SAND SEPARATING APPARATUS.—H. L. HAMILTON, c/o Iowa White Co., 1719 Grand Ave., Des Moines, Iowa. The invention relates to apparatus used in gravel and sand washing plants. The object is to provide a sand separating apparatus arranged to effec-



A REAR SIDE ELEVATION, WITH PARTS SHOWN IN SECTION

tively separate the same from the water without loss of even the finest sand. A further object is to provide an apparatus capable of a large output in a comparaitvely short time and without unduly increasing the operating expense.

## Musical Devices

TAMBOURINE.—I. LEVY, c/o Michthauser & Levy, Java, Provost and Kent Sts., Brooklyn, N. Y. The primary objects of this invention are to so construct a tambourine as to materially reduce the cost of manufacture, and to render the same more durable than tambourines as usually constructed. The instrument comprises an integral flange defining one edge of the main body, and provided with a plurality of cut-out portions, and sound-producing elements mounted in the cut-out portions.

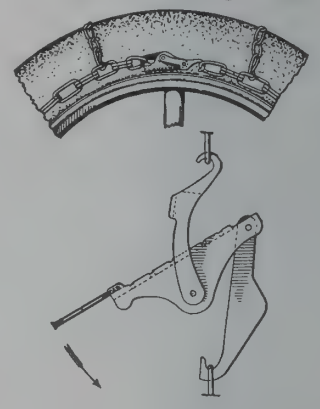
## Prime Movers and Their Accessories

AUTOMATIC FUEL MIXTURE REGULATOR.—A. A. LOETSCHER, Hotel Carlin, Billings, Mont. The invention relates more particularly to an automatic fuel feed regulator for internal combustion engines. An object is to provide an automatic fuel mixture regulator under the control of and responsive to the speed of the engine to effectively vary the proportion of the hydrocarbon or other combustible and of the air whereby the fuel mixture or charge delivered to the cylinders is accurately proportioned for perfect combustion and maximum power at all engine speeds.

BOILER.—J. P. PERRY, Glencoe, N. Y. An object of the invention is to provide a steam boiler design which will have a great deal of heating surface and which will be comparatively small in size, in order to provide a suitable boiler for use on airplanes, automobiles, and other vehicles, and which will also find a use in any capacity where it is necessary to produce steam for operating steam engines and turbines.

## Pertaining to Vehicles

CHAIN CLAMP AND TIGHTENER.—G. J. WIEDMAN and J. H. HUGHES, 202 Mont Bldg., Lewiston, Mont. This invention has for its object to provide a chain clamp and tightener, especially adapted for securing non-skid chains



A SIDE VIEW OF CLAMP PARTLY OPEN, AND CHAIN CLAMPED ON TIRE

on motor vehicle tires, wherein mechanism is provided for easily and quickly tightening the chain and clamp in place beyond the possibility of accidental opening.

BRAKE ATTACHMENT FOR AUTOMOBILES.—H. W. HAAPANEN, 224½ St. Jean St., Detroit, Mich. Among the objects of the invention is to provide a device having elements or shoes which engage with the road bed, for positively stopping the automobile or preventing skidding, and which may also serve as a supporting means to retain the tires elevated from contact with the bed when the machine is not in use.

BASE FOR JACKS.—A. E. HUTCHISON and H. KRAH, 372 Monroe St. Brooklyn, N. Y. This invention pertains more particularly to lifting jacks especially employed as an accessory of motor vehicles. In jacks of this type difficulty has been experienced in maintaining the jack in true vertical alinement during the lifting operation. In this device a rigid base is provided, capable of removal, and with securing means which may be adjusted with respect to the base.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

# The Finishing Touch

At the end of the Dynamite Line is the box packing house. Here Hercules Dynamite receives its finishing touch.

In this house three operations take place. The cartridges are dipped in melted paraffine and made thoroughly moisture proof. They are given a final inspection. They are weighed and packed, and every effort is made to see that each box contains not an ounce less than its 25 or 50 pounds of dynamite.

The hands of the men who do this work are the last to touch, their eyes the last to see Hercules Dynamite before it reaches the scenes of its appointed tasks. Their care, their thoroughness, supplies the final check necessary for the successful use of over fifty million pounds of Hercules Dynamite a year.

* * *

A farmer in Minnesota is clearing a field of stumps. A miner in Pennsylvania is bringing down a breast of coal. Engineers are driving a great tunnel through the heart of the Rockies. In a great city the foundation of a skyscraper is being carved out of solid rock.

Hercules Dynamite is on the job in every case—dynamite which a few short weeks ago passed under the hands and eyes of the men at the end of a Hercules Dynamite Line—dynamite which has made the name Hercules a synonym for dependability in explosives.

"Concrete Floors need not Dust or Wear!"

WHEN we made this statement a number of years ago, it seemed incredible. Many paid no attention to it.

Today there are between one hundred and two hundred million square feet of lapidolized concrete floors which cannot wear or dust.

The laboratories of Sonneborn have given concrete a much wider use in floor construction by creating

LAPIDOLITH
TRADE MARK

the *original* liquid chemical dustproofer and wear preventer which makes concrete even harder than granite by completing the hydration of the cement.

Let us refer you to a lapidolized floor in your immediate vicinity.

## Building Out the Bubonic Plague

(*Continued from page 466*)

an open door and had climbed five stories up an elevator rope.

As a result of the cutting off of their food supply, old, slick rats that had grown wise and cautious became daring and reckless when starved and hungry, and were then more easily trapped and poisoned.

Board sidewalks, old stable and warehouse floors were torn up and nesting and hiding places destroyed. Concrete took the place of wooden walks and floors. Some buildings were ratproofed by the use of concrete walls that extended for two feet under ground, while other buildings were ratproofed by elevation. Sides of doorways were lined with metal so that no rodent could chew its way through.

Warehouses in San Francisco have been vastly improved since the days of the epidemic. Amended building ordinances have provided for concrete floors in basements, ratproof foundation walls and rat screens on all openings in foundations. Owners have found that these improvements were paid for in a few seasons by the elimination of loss from rat depredations and the subsequent saving was clear gain.

It took the united efforts of the people of San Francisco together with the aid of the Federal Government and millions of dollars in money fighting day and night for more than a year before the epidemic was stopped and the last plague-ridden rat destroyed. At times upward of one thousand men devoted their entire time to the work. It was estimated that more than two million rats were trapped, poisoned and otherwise put to death.

Following the outbreak in San Francisco there was an epidemic of bubonic plague in New Orleans in 1914. The latter city however, had the advantage of the experience gained in San Francisco, consequently the work was carried on more intelligently from the start. Notwithstanding this it cost the city of New Orleans eight millions of dollars and fifteen months of hard work in ratproofing buildings and wharves with concrete and metal and destroying rats.

Aside from the danger of bubonic plague, the rat is responsible for an annual economic loss that is staggering, within the confines of the United States alone. The destruction occasioned by these little four-legged vandals is so immense as fairly to bewilder one who reads the figures for the first time.

Mr. David E. Lantz, assistant biologist of the Bureau of Biological Survey for the United States Government, estimated in 1917 that the total annual loss from this pest would amount to at least $200,000,000. With the present greater value of food stuffs and materials that are subject to rat damage, the loss will undoubtedly reach nearer $300,000,000 per year at this time. The yearly rat damage in various cities in 1917 was estimated by the Biological Survey, after careful investigation, for Washington as $400,000; for Baltimore, $700,000; for Pittsburgh, $1,000,000. The Woman's Municipal League of Boston announced in 1917 that the annual loss in that city from rat depredation would amount to $1,350,000.

A professional rat catcher in Los Angeles recently estimated that the number of rats in that city would at least equal the human population. As there are approximately 700,000 people in Los Angeles, one can get an idea of the rat colony in that one city alone. It was estimated by investigators in Los Angeles that the destruction of food and other property by these little marauders would average one and one-half cents per rat per day. In seaport towns where there are extensive wharves as in New York, Boston, New Orleans and San Francisco, there are probably many more rats than people.

The people who live in the country suffer a loss from this source as well as those in the city. In one field of over one hundred acres of corn raised by boy scouts, rats climbed six feet up the stalks to reach the ears and destroyed approximately ten per cent of a large crop.

The brown rat, which is the variety that predominates in this country, owing to its ferocity, strength and fecundity multiplies with alarming rapidity. The young female rat breeds when three or four months old. If food is plentiful, they will breed from six to ten times per year and produce in the middle part of the United States about ten young to the litter. The period of gestation is twenty-one days.

The economic loss caused by the rat concerns us all. It is quite natural for the merchant, the manufacturer and the farmer to include this leakage in their cost of doing business, along with interest on the investment and other overhead expense. They must have some profit in any event. The final goat—the ultimate consumer—eventually pays the bill. But the cities of San Francisco and New Orleans have demonstrated that the rat menace can be effectively checked by building it out.

## Airbrakes for the Automobile

(*Continued from page 467*)

Our first photograph shows the accumulator valve. This water-jacketed valve is usually installed in the priming-cock opening on any one cylinder of the engine and maintains automatically a constant, dependable pressure in the reservoir. A small quantity of air (or spent gas) is forced through the accumulator valve at each explosion stroke until the pressure in the reservoir balances the pressure in the cylinder. The accumulator valve then remains closed until the reservoir is reduced or excess engine pressure is generated. About twenty or thirty revolutions of the engine are required to raise the tank pressure high enough to balance the engine compression. After this pressure is reached, no loss in engine efficiency will occur, but the effect on the engine is not noticeable even when the tank is empty.

When coasting down a long hill, the engine may be shut off as usual, and the compression will generate ample pressure to control the brakes properly. If for any reason the hose should break the brake will be automatically applied.

## Automobile Signals for Danger Spots

(*Continued from page 467*)

switch out of gear before the wheels reach the main operating tread so that the motor will pass on silently in speeding away from the signal and danger.

The signal is designed so that it can be operated either by electricity or mechanical means. The average automobile wheel traveling at a speed of 20 miles an hour remains on the tread only one one-hundredth of a second. On this account it has been necessary to develop a time switch to prolong the action of the signal to from one to ten seconds. In the electrical signal efficient use has been made of a weighted fly wheel operated by a pawl from the main shaft. This four-inch fly wheel is hung on ball bearings and carries a cam for raising or lowering a brush, the arrangement being such that when the fly wheel comes to a balance, the brush is insulated or the current is broken. The ratchet which is worked by means of the pawl has only two teeth corresponding to the balance or rest of the wheel and the occasional dead center which may occur. The end of the pawl clears the fly wheel when it is rotating. Its purpose is to prevent the possibility of the signal light, bell or horn operating continuously if accidentally the tread should happen to be pinned down under a stationary car. The signal itself responds only to a heavy blow and will

not work when only gentle pressure takes place on the tread.

It is to be hoped that this signal will not be robbed of its effectiveness in the same way that the ordinary caution signs have been spoiled, by being posted at all sorts of trivial supposed "danger spots." When one runs over a road which is posted "Danger Ahead," "Caution," "Run Slowly," etc., at the summit of every ten-yard declivity and at the neck of every slightest twist in the roadway, the best intentioned driver in the world cannot help acquiring a feeling of contempt and disregard for these superfluous warnings. They should be reserved for the places that are really dangerous and really more or less blind, so that whenever one comes upon them one may be assured that there is really something ahead, beyond what is immediately obvious. The finest warning in the world is worthless if cheapened as are the danger signs in many parts of New Jersey and Pennsylvania.

In addition to this device, Asheville, as one of our photographs shows, is in enjoyment of a procedure which might well be made universal and compulsory. When the street is wide enough to permit it, practically all municipalities require parking of cars perpendicular to the curb instead of parallel thereto, since this at the same time makes it possible for any car to get in and out without disturbing other cars, and furnishes accommodations for considerably more cars. But in most places where we have observed this convention, it is customary for the cars to back in to the curb and park front to the street. Asheville, as our picture shows, enforces the reverse procedure, which is altogether good, since it is much easier to run into the narrow passage between two cars when going forward, while the process of getting out again, once the car is in, is equally easy whether performed forward or backward. This is a convention which might well be universally copied.

## Putting the San Joaquin to Work

(*Continued from page 470*)

dation for the dam, the entire stream of the San Joaquin River was diverted by excavating a cut 30 feet wide and 250 feet long, the water being led away by a flume carrying the water to a point below the dam, after which the water again resumed its nature channel. This diversion enabled the men to work in the dry bed of the stream, and construction was pushed with great speed. The dam is built in the form of an arch, and is approximately 36 feet thick at the bottom, and has a maximum radius of 200 feet. Across the entire crest of the dam are mounted Taintor gates 20 feet in width and 14 feet in height, through which the entire flow of the San Joaquin River during flood can be handled without backing up the water to interfere with the operations of plant No. 1 of the company, approximately 2½ miles upstream. Power for the construction work was secured from this plant.

Material for the concrete work was obtained from the immediate site of the dam, as excellent supplies of rock were found there, and a crushing plant, with a capacity of 25 yards per hour, was installed. By placing this crushing plant on the side of a hill all the material handled was moved by gravity through chutes, placed at 55 degrees slope, thus avoiding the necessity for elevators.

A fleet of 14 motor trucks of from 2 to 5 ton capacity carried the freight from the nearest railroad to the incline tramway, and since it was found necessary to sprinkle the roadway on account of the dryness of the earth, a pipe line was laid along the entire distance of road built and water wagons kept the dust laid at all times.

Work on the tunnels was carried on at five different points simultaneously, and as removing the tunnel muck proved too slow by hand, steam shovels were in-

# He Tore Up the Blueprints

THE chief engineer of a $5,000,000 plant in one of St. Louis' new industrial districts prepared plans and specifications for an $800,000 generating station to supply electric current. He figured that an immense quantity of refuse which could be used as fuel in the generating station would be provided in the daily operation of the plant

Inquiry developed that St. Louis has a dual supply of cheap hydro-electric current and steam-generated energy in plentiful quantity to serve all industries that locate in St. Louis. The company found that St. Louis is girdled with an interlocking transmission system between the two sources of supply, giving interconnection through eight substations strategically placed throughout the city.

The company was convinced. The engineer tore up his blueprints. The plan to build an $800,000 generating station was abandoned. The company found that it could dispose of its fuel refuse in other ways and buy its power current in St. Louis cheaper than it could generate its own supply through the use of the refuse.

## St. Louis Has Abundant Electric Power

One of the essential factors in industrial development these days is an ample supply of reliable electric energy sold at rates which enable manufacturers to use it in large blocks economically. St. Louis is in a remarkably advantageous position in this respect. It has a large capacity of electric current from the Keokuk Dam and a local steam generating plant located directly on the Mississippi River.

Among the industries now being furnished with electric energy from St. Louis' plentiful supply are shoe, ice, automobile, drug, iron and its allied industries, drying ovens, brass and enameling ovens, electric steel and gray iron furnaces, mills and factories in almost every line of industry.

St. Louis can furnish ample electric power for any of the following sixteen industries for which there is need and a profitable market in the St. Louis trade territory:

*Cotton spinning and textile mills*
*Steel and copper wire*
*Machine tools and tool machinery*
*Automobile accessories and parts*
*Tanneries and leather goods*
*Shoe laces and findings*
*Malleable iron castings*
*Screw machine products*
*Farm implements*
*Rubber products*
*Locomotive works*
*Blast furnaces*
*Cork products*
*Small hardware*
*Dye stuffs*
*Drop forge plants*

# RELATIVITY

## The Special and the General Theory

By Professor Albert Einstein, Ph.D. LL.D.

Translated by Professor Robert W. Lawson, M.Sc.

THE authorized English translation of Einstein's own book explaining his theories to the general public is now available. Dr. Einstein has scored a conspicuous success in this volume, steering a skillful course between the twin dangers of too much mathematics and too little explanation. Also, he makes clearer than has yet been made just wherein lies the dividing line between his special theory and his general theory, and just where the two join. In literary style as well as in clarity of exposition this book bids fair to take rank as a classic; and in any event, it is by far the most satisfactory treatment of the subject to be had at the presen date in English.

stalled and these loaded directly upon dump cars which were hauled away by electric locomotives, trains being made up of five or six cars. Except where water was encountered in large volume, some of the tunnel crews made as high as 12 feet a day, and the work of drilling and mucking went on simultaneously. A heading, approximately 8 feet high and the full width of the tunnel, was carried approximately 7 feet ahead of the bench. As soon as the shooting from a preceding shift had been completed, the steam shovel men immediately commenced to load out the muck which had been blown back from the face. The machine men and chuck tenders at the same time start work on the top of the muck and shovel back the material which still remains on top of the bench. By carrying a short bench, it is possible to clear the same with a minimum amount of hand mucking, thus enabling the drilling in the face to proceed at the same time that the steam shovel is mucking out the heading. This makes it possible for the tunnel work to proceed through the entire 24 hours of a day.

At one of the tunnels a different method of work was adopted. Here the crews were divided into drilling and mucking gangs, and worked separately. A car was specially built upon which was mounted a column 17 feet high with a jack on each end, with 4 cross bars mounted on the same, the drills being mounted on the cross bars. By this method the entire face of the tunnel was drilled and shot before the steam shovel started to work, and each crew worked in shifts. By this method a maximum speed of 90 feet in one week was obtained. Considerable rivalry existed between the various crews, and as the progress made by each crew was posted, the men working in the different tunnels endeavored to outdo each other with the result that excellent progress was made in all departments.

The three penstock lines are of riveted steel pipe, 7 feet in diameter at the lower end and 8 feet in diameter at the upper end, at which point they are concreted into the mouth of the tunnel. A forebay 17 feet in diameter at the top, 80 feet in height and 40 feet in diameter at the top of the tunnel, has been excavated in solid rock a short distance from the outlet of the tunnel, where the penstock joins the same. The purpose of the forebay, from which a spillway leads to the river, is to take care of surges due to sudden increases and decreases in load at the plant.

From the power house a 110,000-volt transmission line about 75 miles in length carries the current to a point near Tulare Lake, where it is delivered to the distributing system for use where needed. Since the hydroelectric lines of all California companies have been connected up for emergency use, it is possible to send power generated at one point to any part of the State for use.

### The "Super-Destroyer"

(*Continued from page 472*)

the guns, including director aiming and firing mechanism. It is, however, doubtful whether all this cumbersome and intricate gear was suitable for vessels which were simply enlarged destroyers, and therefore exposed to the sort of rough and tumble fighting in which headlong dash counts for more than science. Moreover, experience in other navies shows that the 5.9-inch gun, with its 101-pound projectile, is much too heavy to be conveniently manhandled on the slippery decks of a boat which is moving all ways at once. In theory, the German "V-116" leaders ought to have made short work of any destroyers they were likely to meet in the North Sea; in practice they would probably have been beaten by the smaller British boats armed with the handy 4-inch and 4.7-inch gun.

A particularly formidable type of flotilla leader is represented by the five new Japanese boats of the Akikaze class, building under the estimates for the current year. They will displace 1,900 tons and have a speed of 38 knots. Four, or possibly five, 5.5-inch 82-pounder rapid-fire guns will be mounted on the centerline, and all six torpedo tubes can be trained on either beam. A feature of these boats is their large fuel capacity, which is expected to give them a cruising radius of 3,500 sea miles at economical speed.

It will be seen that the modern flotilla leader approximates to the light cruiser in dimensions and armament. If the recent rate of progress is to be maintained, "boat" will soon become a misnomer, and we shall revert to the "torpedo cruiser" of thirty years ago, though on a much larger scale. In the destroyer and flotilla leader, as in every other type of fighting craft, each new demand for increased armament, speed and sea endurance involves a corresponding increase in size, and there is practically no limit except in the paying power of the nations concerned. But in every class of fighting ship there comes a stage of development which fulfils all reasonable requirements, and beyond which it is unnecessary to go. In the case of the flotilla leader this stage appears to have been reached in the smaller designs set forth in the table shown. War experience has demonstrated the all-round tactical efficiency of such vessels as the British Scott class, which, on the relatively modest displacement of 1,740 tons, combine in a high degree the essential qualities of a destroyer flagship. It is of interest to learn that a tentative design prepared at Washington last year provided for a vessel of 1,800 to 1,900 tons, of 37 knots speed, armed with four 5-inch rapid-fire guns and eight torpedo tubes.

### Golf Without a Caddy

(*Continued from page 473*)

in fact works out much more wisely than anticipated; when a few ounces can save upward of 25 tons as above, the ounces are certainly working at some high efficiency Think of the perspiration and utter exhaustion that would overtake one were he compelled to go out and raise 25 tons to the height of 1 foot by hand twice a day. How much of either energy or inclination for golf would a man have after such an exertion, or by taking the stairs climb about 30 stories in one of our tall buildings twice a day? And this is exactly what caddiless golf has been doing to us without our ever suspecting it.

With the little device I have referred to, the simple act of resting the bag down on the ground causes it to develop legs which keep it upright and very stable, and with my eye on the ball and without looking around, I am able simply to reach back, grasping the bag, and the act of lifting it from the ground causes the legs to disappear and the bag looks like any ordinary "Sunday" bag and is little or no heavier.

Another point that I have found important is the following: We all know that "keep your eye on the ball" is even more necessary after the shot is made than while making it, *if you have no caddie.* It is then the player's job to watch the ball—certainly no caddie is watching it for him. Again, one often loses the lie of the ball in the rough while stooping down to get his sticks, thus causing exasperating delays. I have found that it is certainly of surprising convenience to have the sticks right at hand, standing upright "on their toes," so to speak; and to simply reach back, grasping the bag while watching your ball, and be off on the next stroke toward the drop long before the ball lights. This is of great aid in holding your position on the course and I find often aids a whole foursome to hold its position in play. The unerring location of, and getting right off on the ball is certainly an aid, both directly and indirectly, that can hardly be overestimated.

**Put On Like Plaster—Wears Like Iron**

It is a composition material, easily applied in plastic form over old or new wood, iron, concrete or other solid foundation --Laid 3-8 to 1-2 in. thick--Does not crack, peel or come loose from foundation.

It presents a continuous, fine grained, smooth, non-slippery surface, practically a seamless tile--No crack, crevice or joint for the accumulation of grease, dirt or moisture--is noiseless and does not fatigue.

**The Best Floor**

for Kitchen, Pantry, Bath Room, Laundry, Porch, Garage, Restaurant, Theater, Hotel, Factory, Office Building, Railroad Station, Hospital--all places where a beautiful, substantial and foot-easy floor is desired.

## Sending Photographs Over Wires

(*Continued from page 474*)

say, at one end it is absolutely opaque, but going toward the other end it becomes steadily more transparent until it reaches practical transparency. Thus the stylus attached to the microphone at the transmitting end is at a given moment on a black or high spot of the cylinder, and transmits a heavy current over the line; and this heavy current at the receiving end causes the mirror to be so pointed that the beam of reflected light strikes the opaque end of the finely graduated screen and thus fails to make an impression on the sensitized receiving cylinder. In this case the receiving cylinder will receive an impression, and using it as a photographic negative any number of positive prints can be made. It also follows that if the graduated screen is reversed, or if the polarity of the Blondel oscillograph is reversed, the receiving cylinder can be made a photographic positive.

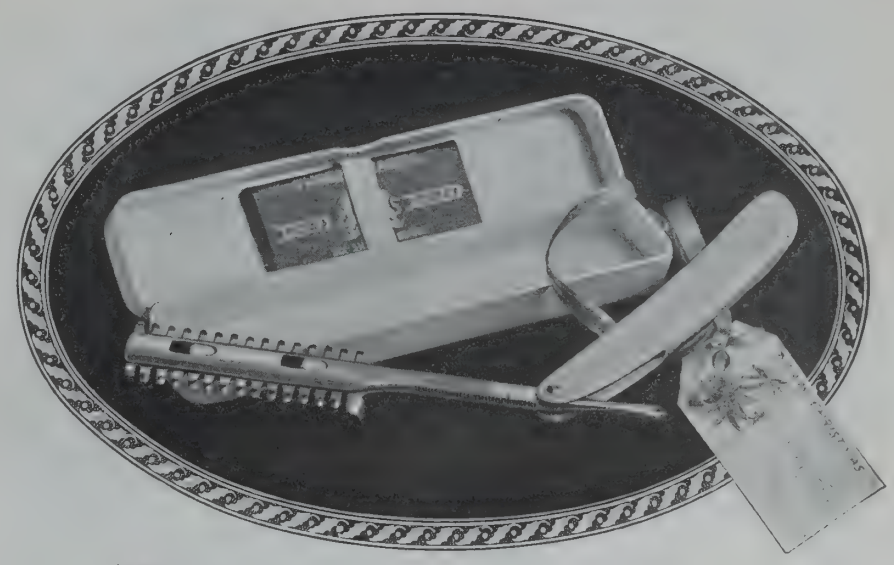
So much for the general details, but there are numerous refinements, as might well be imagined, in an apparatus capable of accomplishing such delicate work. The aperture through which the beam of light passes on to the receiving cylinder is of microscopic proportions and is made in a silver disk which presses against the recording surface. This hole is of a size corresponding to the pitch of the feed mechanism, so that the light record, made in the form of a continuous spiral, has its threads so close together that it forms to all intents and purposes a solid photographic exposure. Otherwise the spiral would have marked spaces between the turns, which would destroy the usefulness of the received photograph.

Obviously, the transmitter and receiver must operate in step or in perfect synchronism, otherwise serious distortion results. To this end a special device is used at the transmitting end, for the purpose of starting the cylinders at both ends at the same time. When one cylinder gets a little ahead of the other, a special arrangement causes its retardation until the other cylinder has caught up so to speak. This feature of the system comprises special contact members and solenoids.

The cylinder of the receiving apparatus can take a piece of film or a strip of sensitized paper, and the emulsion of either can be of such speed as to take care of the rate of operation. The cylinder is contained in a metallic case of octagonal shape, the loading of same being accomplished in a dark room. By means of a number of cylinders and containers, the receiver is operated in a manner quite suggestive of the conventional camera and plate-holders.

Regarding the rate of transmission, which is obviously an all-important factor when the main arteries of the world's communication system are to be leased for the purpose of transmitting photographs, M. Belin tells us that this is a question of quality and fineness of detail. Some photographs are not so detailed as others, hence the transmission can be done on a somewhat coarser scale. And even the finely detailed photograph can be transmitted at a faster rate if it is permissible that the copy at the receiving end be of coarser quality. Detailed photographs can be faithfully transmitted in from four to eight minutes each, while coarser photographs or those which require rapid transmission can be handled in three to six minutes. M. Belin hopes for even more rapid transmission in the near fuure.

Something has been said about another contact-making device, indicated by *C* in one of our photographs. This device is intended for the transmission of matter in straight black-and-white, as distinguished from the half-tone graduation of photographs. In this case a given piece of writing, type matter or drawing is transferred on to the copper cylinder with the aid of a special ink, thus leaving a raised impression after drying. The contact-making member *C* is simply a make-and-



**Money can not buy a finer Christmas gift**

# Aerial Transportation

Overhead, out of the way of ordinary traffic, the conveyor of the Aerial Wire Rope Tramway makes regular trips between loading and unloading stations, unaffected by mud, ice, sleet or snow.

This form of transportation, so economical under certain conditions, was not practical until the manufacture of wire rope became a commercial reality.

Now, Aerial Wire Rope Tramways are used very generally in transporting coal, ore, logs, rock, sand and many other materials from where they are to where they are wanted. Their scope, already broad, has been greatly extended by the scarcity and high cost of labor.

In addition to being pioneers in the manufacture of wire rope, for many years the Broderick & Bascom Rope Co. has designed Aerial Wire Rope Tramways of every type, and erected them in practically every part of this country, in Canada, Alaska and Mexico. Much of their success has been due to the efficiency of the Broderick & Bascom track cables and pulling lines with which they were equipped.

There is a grade of Broderick & Bascom Wire Rope best suited to every purpose. Our YELLOW STRAND, distinguished by having one strand painted yellow, is not excelled in strength and serviceability by any other rope.

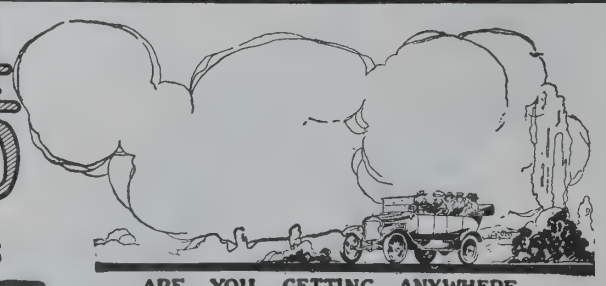
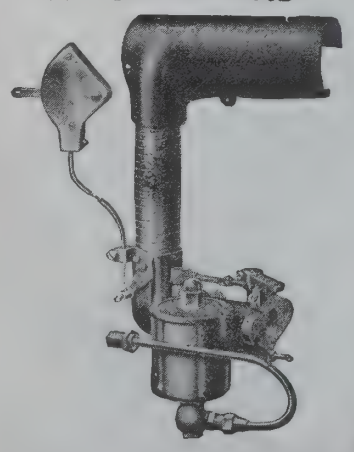
C485A

# 37 4/10 MILES ON A GALLON OF GAS





ARE YOU GETTING ANYWHERE NEAR THAT—FROM YOUR FORD?

Suppose you are getting twenty-two miles on a gallon of gas. Then, suppose you increased that mileage to THIRTY. There are eight miles of added travel—motoring that didn't cost you a red cent more than you are now paying—a reduction of approximately *thirty-three and one-third per cent.*

The new Stromberg Carburetor for Fords HAS caused just such astounding cost reductions for tens of thousands of Fords.

It established the World's official economy record. A mileage feat that has never been equalled—37 4/10 miles on a single gallon of gasoline.

Ready for immediate installation. Equipped with new improved easy starting attachment. Call on your local dealer or write us for descriptive matter. Beat the high cost of gas. Make your Ford a far more dependable and a far more economical car than ever before.

**STROMBERG MOTOR DEVICES CO.**
**64 East 25th Street Dept. 1116 Chicago, Ill.**

New STROMBERG CARBURETOR Does it!

break device actuated by its stylus pressing against and in constant contact with the copper cylinder.

At the receiving end the graduated screen is replaced by an opaque screen which has a single vertical slit. This arrangement means that the mirror has only two positions so far as the sensitized receiving drum is concerned, namely, shining through the slip and on to the sensitized surface, or striking the opaque plate and thus making no impression on the sensitized surface. In this manner straight black-and-white matter can be transmitted at a high rate of speed and the reproduction must necessarily be quite faithful. M. Belin told the writer that he had transmitted cartoons, manuscript and type matter with excellent results. Photographic proofs of printed or other matter measuring four by six inches can be transmitted in four to eight minutes, and M. Belin has under construction machines which will assure the transmission of 10,000 words of text in printed form per hour.

Aside from its application to modern journalism, which is obviously the main purpose to which all electro-photographic transmission systems can be put, there are other uses. One which suggests itself to us is in the transmission of police photographs for the identification of criminals. Such a use would prove invaluable in the running down of criminals. Then there is a distinct legal use for such a system, in the transmission of facsimile evidence, signatures, and so on. There is also a military use. Perhaps, too, the system might be put to public use, permitting anyone to transmit photographs over telegraph and telephone wires to distant friends, although it would seem that the cost of such messages must remain quite high for a long time to come.

The same system can be applied to radio, by coupling the Belin apparatus with the usual arc, high-frequency alternator, vacuum tube or other type of continuous-wave transmitter. All in all, this system is applicable wherever wires or wireless or even cable is now employed in the transmission of human thoughts.

## Recent Patent Decisions

(*Continued from page 476*)

away with the annoying tintinnabulations, is entitled to protection, where the specifications disclose the method, even though the inventor is ignorant of the scientific principles involved.

Where a person, by anything which he does or says, or abstains from doing or saying, when it is his duty to act or speak in respect of a subject matter, intentionally causes or permits another person to believe a thing to be true, and to act upon such belief otherwise than he would have acted but for that belief and he so acts, and materially changes his position in respect of the matter to his detriment, then the first person is not allowed, in a suit between himself and such other person, to deny the truth of the thing done or stated. Also, delay in prosecuting other infringers while the validity of a patent is in active litigation does not constitute laches or negligence. —*Searchlight Horn Co. v. Victor Talking Mch. Co. U. S. D. C. of N. J.*

**Patents Used by Contractor.**—This is an appeal to the Court of Last Resort of Arizona, and the decision and opinion of the Supreme Court of Arizona touches upon a matter involving patent law. The case was one brought by sureties on bonds against a street cleaning contractor concerning a series of controversies involving many issues.

It is held that a patentee or owner of a patent has the right to charge a reasonable royalty or license fee for the use of a patented material or process, and that without procuring from the patentee or owner of a patent the right to use the patented material or process there can be no lawful use thereof. Royalties due from a contractor for the privilege of using a patented process for combining materials used in bitulithic paving, and machinery used in connection with laying such material, held covered by the contractor's bond conditioned on contractor's payment for materials furnished for the improvement. That the owner of a patent process did not file agreement to furnish all the material and give license to use of patents at definite price as required by specifications did not preclude the owner from recovering from contractor's surety for royalties due where the price was reasonable and neither the city nor property owners objected.—*U. S. Fidelity & Guar. Co. v. Calif.-Ariz. Const. Co. et al. Supreme Court of Ariz.*

## Eliminating the Flash From Rifles and Big Guns

THE production of smokeless powder at once rendered the art of locating the enemy's batteries comparatively difficult. However, such location often remained possible at night because of the flash observed upon the firing of the gun. A French scientist, M. Delpech, now proposes to suppress these telltale flashes, and his report upon the matter was not long ago laid before the French Academy of Sciences.

The ball of flame which is formed at the mouth of the gun is a result of the violent and instantaneous combustion of masses of carbon monoxide and of methane, which take fire upon coming into contact with the air, where they form a detonating mixture with the oxygen of the latter, whereupon a second explosion produces the luminous flash. If experiments be made with a "75" gun for example, with different powders, it will be seen that the flash of light is always produced with powders that employ at a high temperature of combustion, while with powder employing a lower temperature of combustion the flash is diminished in intensity. When a naval "75" which is longer, is desired, the gases are not ignited, since they are too much cooled by their passage through the longer barrel. In the same manner it is found that the same gun cartridge will produce a flash or not produce it according to whether the barrel of the rifle is short or long. These observations at once suggest the method by which the flash may be suppressed—in one way or another the gases must be cooled. One way of doing this is by adding, to the charge of powder, salts which contain water of crystallization and therefore exert an anti-thermic effect. Or the cooling may be accomplished, on the other hand, by physical instead of chemical means; and M. Delpech has demonstrated that the flash can be extinguished by the addition of 20 grams of vaseline to the charge of powder. In certain kinds of guns it is sufficient, indeed, merely to apply a plentiful coating of grease to the projectile. No change either in the pressures or in the speed of projection takes place but the flash is extinguished.

The suppression of the flash is more difficult in the case of big guns, because the mass of gas formed is so enormous. But it can be successfully accomplished, according to this investigator, by greasing the entire surface of the cartridges with grease or vaseline (20 per cent of the weight of the powder). These flameless powders were first obtained in 1917, and have given entire satisfaction ever since the time when at M. Delpech's suggestion the diminution in the liberation of heat was compensated by a corresponding increase in the weight of the powder (4 per cent). The anti-flash effect is obtained by introducing 2 per cent of vaseline into the powder. The suppression of the flame is complete with the guns experimented upon. The vaseline in no way modifies the firing action, the pressure and the rate of speed remaining unaltered; furthermore, the vaseline is found to exert a powerful stabilizing action upon B powder.—By *M. Tevis.*

## Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.

(14345) W. S. A. writes: I was interested in Lieut. C. C. Harshman's account of "A Moonlight Rainbow" in your issue of July 3rd. This phenomenon is considered to be rather rare, but I saw one in England many years ago. This was a perfect bow, but lacked the coloring seen in the solar rainbow. I have always understood that lunar rainbows are colorless, but Lieut. Harshman does not refer to this feature in his account. A. Lunar rainbows are rare occurrences. The moon must be near its full and not far above the horizon for one to be seen. The bow will be on the opposite side of the horizon from the moon. Lunar halos are frequent on the same side as the moon. If early in the evening the bow will be in the west and the moon in the east. The writer has seen two lunar bows, both in the same evening, and about a half hour apart; faint colors could be seen red and yellow as he recollects. Never more than three are recorded, red, yellow and green, and it may be that some of these are to be ascribed to the imagination. As the writer recalls it, the lunar bow is spoken of in a very old book, "The Phenomena of the Four Seasons," by President Hopkins of Amherst College. He says in substance that a person may not expect to see more than one in a lifetime, ranking it with the wonderful coloring of autumn leaves, and a grand ice storm of winter with all the colors of the spectrum brought out in the ice crystals by the sun shining upon an earth covered with wonderful crystals.

(14346) J. C. asks: Could you please tell me the critical temperature of hydrogen, carbon, boron, aluminum, or any element? Understand I mean the *critical temperature.* 2. Could you state the thermal energy of the sun per square yard at our earth's equator? 3. Could you give me any information on the way the American Telephone Company has so increased the voice amplitude in apparatus? Is it by means of a new coil in wiring—as there are only two coils in wiring, to wit: Henry's coil and Pupin's coil—do you know if there's a new coil brought out by the aforementioned company's engineering staff? A. 1. The critical temperature of hydrogen is given in the Smithsonian Physical Tables as —240°.8°C. and the critical pressure is 14 atmospheres. There are no critical temperatures given for the other elements which you name: carbon, boron and aluminum, in the tables quoted above. Critical temperatures belong only to gases and these elements vaporize only at very high temperatures. Aluminum boils at 1,800°C., carbon is computed to boil at 3,600°C. and is known to volatilize without melting in the electric oven, while boron volatilizes without melting in the electric arc, the temperature of which is that of the carbon vapor which conducts the current across the space between the electrodes by its ionization at not less than 3,500°C. The figures given are from the tables quoted above, excepting the last for the temperature of the electric arc. 2. The Solar Constant of Radiation, as it is termed, is about 1.95 calories per square centimeter per minute, as given in the latest book upon the subject, "Abbott's Sun." Dr. Abbott is director of the Smithsonian Astrophysical Observatory and our highest authority on the subject. This number is the same for any place on the earth since it is the heat energy outside of the atmosphere received by a surface at right angles to the rays of the sun. Of this quantity perhaps 5/8 reaches the earth's surface, the rest being absorbed by the atmosphere. Of course the amount of absorption varies with the dust in the air and the angle of incidence upon the surface of the earth. 3. The amplification of the telephonic current is not produced by coils principally, although transmission to a distance was brought about by Pupin by securing resonance of the telephonic circuit by the addition of coils to the circuit. Amplification is

**HARD RUBBER**
**AN ESSENTIAL INDUSTRIAL RAW MATERIAL**

MEN who appreciate the friendliness of a good pipe know that there is nothing quite so satisfactory as a Hard Rubber bit They like its comfortable, sure grip which will not injure the teeth. They realize the sanitary, non-absorbent character of its surface.

Leading manufacturers of smoking pipes come to the American Hard Rubber Company for pipe bits, knowing that several generations of experience devoted exclusively to Hard Rubber help make it possible to guarantee the excellence of their Pipes.

Besides Pipe Bits, Cigar and Cigarette Holders, AHRCo. Hard Rubber is essential raw material for hundreds of useful articles.

# MONARCH LATHES

The Monarch Organization is proud of the fact that it builds and sells more Monarch's each year than there are lathes produced by any other high grade manufacturer.

And the Monarch Organization is more proud of the fact that a large percentage of their lathes are sold to present users of Monarch lathes who purchase for replacement or additional equipment. It is the real proof of our policy of guaranteeing "Satisfaction to the Purchaser".

# *The Army and Navy Journal*

**"The Newspaper of the Services"**
Established 1863
*Published Weekly*

FOR over half a century, ***The Army and Navy Journal*** has been accepted, both at home and abroad, as the leading military and naval publication of the United States.

For all interested in the Army, the Navy, the National Guard and Reserve Corps, it presents each week a complete record of the news of the Services, of official orders, personal notes and all military and naval matters.

*For the advertiser* the ***Army and Navy Journal*** *covers completely the service field.*

The strength of the *Army,* including September figures: Officers, 15,168; enlisted men, 190,472: total, 205,640.

The strength of the *Navy,* including September figures: Officers, 12,043; men, 112,087; total, 124,130.

The strength of the *Marine Corps,* including September figures: Officers, 1,065; enlisted men, 17,350; total, 18,415.

The *National Guard,* which is rapidly increasing in strength was to September 30, 1920: Officers, 2,642: men, 62,903; total, 65,545.

***Subscription price $6.00 per year.***

***Special rate of $4.00 per year is offered for individual subscriptions from those now or formerly in the Federal or State Service.***

***Advertising rates on application.***

due to the vacuum bulb or audion, which is the invention of Dr. Lee DeForest. The radio engineers of the Western Electric Co., the U. S. Bureau of Standards and others worked out the system during the war by which wonderful amplification of the voice in the telephone and the wireless telephone became possible.

(14347) H. J. S. asks: Will you be kind enough to send me information on the following? From time to time there have been articles published in newspapers and magazines concerning the so-called "Edison Star." This star was supposed to be sent up from the Edison laboratory. The fact has started quite a discussion and while I read several articles including one of recent date by Garrett P. Serviss in the N. Y. American stating no such thing ever existed, the question remains unsettled. Will you be kind enough therefore to advise me whether or not such a star exists or ever existed? A. While Mr. Edison was working out his system of electric lighting at Menlo Park, New Jersey, some bright intellect started the story that he was in the habit of hoisting a light at early candle light and lowering slowly a little later in the evening. This light was actually seen from New York, it was said in the west. This was Mr. Edison's star. The light was seen in the west all right, but it was not an electric light over Mr. Edison's laboratory. It happened that at that time the planet Venus was bright in the western sky a little after sunset, and slowly sloped to the west setting in late twilight. It was the evening star which gave currency to the tale of the brilliant inventor of the story. This was in 1873-1876, and it seems the story is not dead yet. Nor is it likely that the truth will now overtake the lie. Professor Serviss is quite right, although he makes no explanation.

(14348) W. G. C. asks: I have read many times the theory given for hail storms, the idea being that the wind blowing in a rotary motion carries the rain drops high up in the cold air and back again into the rain cloud and so on but I have never seen any reason why we should get our hail storms after very warm weather for several days. The idea occurred to me that during very warm weather a large amount of very dry air might rise and gather high above the earth. When a shower comes up and rain falls through the very dry air this air absorbs a large amount of moisture or really produces rapid evaporation and intense cold on the same principles as the evaporation of gasoline in the auto carburetor produces cold. My idea was that rain passing through this layer of air after it had been chilled and absorbed all the moisture it could would be frozen and fall as hail. Could this be possible? A. The theory that hail stones are carried up and down several times before fallin from the cloud is based upon the fact that there are usually in them several layers of ice separated by softer material, more like snow. It seems necessary to suppose that the mass has passed from a colder to a warmer region several times before it bcame heavy enough to fall out of the whirling air. It is not thought that fhe ball passes from one whirling mass of air up into another but that it is whirled up and down in the hail cloud itself. It would be difficult to see how the stone could pass out of the whirl in which it was borne into dry air and back again to be carried up and down in this way several times. That it takes on material which is frozen hard after it is received can hardly be doubted. It may be that your conception of a mass of hot and dry air below the cloud is correct. It can easily be worked into the ordinary theory of the formation of hail stones. Any theory must account for the several layers of harder ice which are found in the large stones by cutting them open.

(14349) T. D. asks: Can a sail boat be sailed so that it will travel faster than the wind, if so, how will it be headed? Will a sail boat travel faster directly with the wind than in any other position? A. A sail boat cannot move through the water as fast as the wind which drives it, since it must move its own weight of water out of its path every time it moves its length. A sail boat makes its best speed with the wind abaft the beam, or on the quarter as it is called. This subject is fully discussed and figures given for different sizes of boats in the leading editorial of the SCIENTIFIC AMERICAN of July 31, 1920.

(14350) H. J. P. asks how to refine platinum filings. A. Spread out filings on a large piece of paper and go through carefully with a pair of tweezers to get any solid pieces of gold and platinum, then sift well through a strong steel magnet. Speaking of magnets, see that there is plenty of strength; do not

*Economy was the first line using an inexpensive bare link for restoring a blown fuse to its original efficiency to be Approved in All Capacities by the Underwriters' Laboratories*

use an old one that may have been in a factory a number of years and be played out. Having gotten a good one, always keep a piece of steel on the two ends to keep the magnetinsm from running out. In passing the magnet through small atoms of gold and platinum will adhere to the iron or steel filings. These may be put into an old pickle crock (sulphuric acid and water), which will eat the iron or steel and precipitate the precious metals. When a sufficient quantity is recovered these filings are placed with the others for separaitng. If a lot of oily waste, buffs, etc., are in the stuff to be refined, the same should be put into an iron pot or large iron frying pan and burned out over a gas plate before putting the magnet through. After separating, place in a large evaporating, porcelain dish and to every ounce of filings add three ounces of chemically pure muriatic acid and one ounce of nitric acid. While any quantity of filings may be treated yet it hardly pays to put less than 20 ounces through at a time. If filings are largely gold, the acids, which are previously mixed in the proper proportions, should be added slowly and a little at a time for a rapid action would result in the mixture rising and spilling over the edge, thereby losing some of the metals. The dish should be placed on a sand bath over a gas plate burner and should be kept hot. A glass funnel may be placed over the dish to prevent loss. When all is dissolved, which may be ascertained by stirring with a glass rod, turn off the gas and let cool. Then pour into large crock in which are ten or fifteen quarts of rain or distilled water or water which has been boiled and cooled. Let stand a few hours, or until next day, and a precipitate will be found on bottom of crock. This is chloride of silver. Carefully siphon liquid into another crock, or pass through a funnel with filtering paper to recover any articles or silver which may be still in the liquid; mix up about 20 ounces (for 20 ounces of refinings) of fresh powdered sal ammoniac in a little water, pour in liquid and stir well. In a few hours the platinum will be found on the bottom of the crock. The liquid is siphoned off into a fresh, clean crock, filtered to recover any further traces of platinum and with the precipitate well dried and subsequently melted in the regular furnace. The gold is recovered from the liquid by adding about an equal bulk of water and dissolving about 20 ounces of sulphate of iron (green copperas) in a little water, add and stir thoroughly. Let stand for a few hours, pour or siphon off liquid and the gold will be deposited in bottom of crock in the form of a muddy brown sediment. This is collected, dried and melted in regular crucible. The liquid will contain traces of all the metals, also the copper used in alloying, so should be poured into sink for further recovery by the refiner. The metals recovered this way are not chemically pure, only commercially so, and are used in the general run of jewelry manufacturing. It is safe to assume that in the melting of platinum all traces of silver, copper, etc., are destroyed as the high temperature would cause these metals to volatilize so that only probably metal remaining would be iridium. Sometimes this metal is not dissolved and it is thrown down with the silver. To separate, dissolve the silver in nitric acid only, dilute well with water and hang in a few pieces of copper, old boiling out pans will do, and in a day or two the silver will be thrown down when it may be dried and melted with a little borax. The iridium, trace of platinum, etc., not being attacked and dissolved by the nitric acid are recovered from the bottom of crock and melted. If all details are carefully carried out, the average shop can get out its own filings. In mixing and adding filings to acids in the first operation, the acids must be well heated before action, especially on platinum, takes place. The acids must be well put in dish first, well heated and the filings sifted, in a little at a time, stirring well with a glass rod, so that metals are constantly exposed to the acid. The amounts of sal ammoniac and copperas (20 ounces each) are for about a like weight of the metals and should be, of course, reduced or increased in proportion. All work with acids should be done in a separate room or where there is a large chimney to carry off fumes. Some refiners use oxalic acid in place of the sal ammoniac; results are the same. To be sure of getting strength it is best to buy sal ammoniac in lump form and pulverize it as mortar is required.

(14351) A. D. McN. asks: Will you please tell me whether creosoted wood is an electrical conductor or an insulator. A. Creosote is an insulator, and wood treated with creosote would have higher insulating value than when untreated.

# NATIONAL FACTORY SYSTEMS

COUNTING FACTORY FINDING "FILING" STOCK
MATERIAL TRUCKING MEN WANTED AND MATERIALS

## The Machine That Takes A Minute To Save An Hour
## *SAVES DAYS ON INVENTORY*

DURING inventory the saving of time and labor is tremendous when the thousands of items in stock and store rooms are counted in bulk on National Counting Machines. Not only is there a difference of days in time but the counts are more accurate than can possibly be obtained by hand or by any known method of computing or estimating. National Counting Machines will count anything from feathers to forgings—or show lineal or square foot contents. They are built in 27 types and sizes.

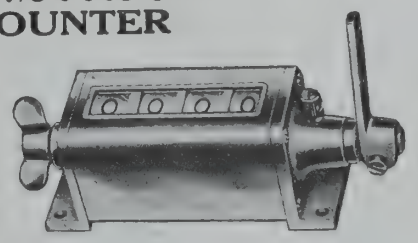
## NATIONAL COUNTING MACHINES

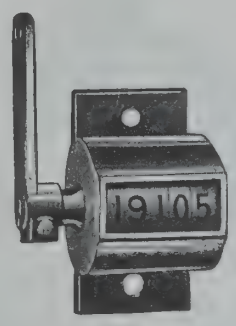
# To Make Safe Your Margin

If a falling market cuts into your profit, cut out waste of work-hours on machines where no work-*records* are kept. Bring down the labor-cost by setting down the operator's *production*—automatically raising the volume with a

**Veeder COUNTER**

*The large Set-Back Revolution Counter at right is less than ½ actual size. The small Revolution Counter below is shown nearly full size.*





The Set-Back Revolution Counter above records the output of the larger machines where the revolution of a shaft registers an operation. Counts one for each revolution, and sets back to zero from any figure by turning knob once round. Supplied with from four to ten figure-wheels, according to purpose. Price, with four figures, as illustrated, $10.00 (subject to discount).

The Small Revolution Counter at left records the output of smaller machines where a shaft revolution indicates an operation. Though small, this counter is very durable; its mechanism will stand a very high rate of speed, making it especially adapted to light, fast-running machines. Will subtract if run backward. Price, $2.00.

*Everywhere that conditions demand economy in manufacturing, Veeder Counters can serve—there's a model for every machine. Booklet with complete line free on request.*

**The Veeder Mfg. Co.,** 18 Sargeant St. Hartford, Conn.

## *Which Case Is Yours?*

Here are five men who found a solution to an unanswerable problem in the

## Emerson Course in PERSONAL EFFICIENCY

Read their letters at the left and then remember that these are only five out of 45,000 who have already enrolled. Each of the 45,000 is getting what he wants most.

Harrington Emerson acquired in practical work with many corporations the knowledge and experience that enabled him to write this course. He is the President of an Efficiency Company directing efficiency work in a number of corporations. In his work he has had to teach and train many young men, some of whom today hold highly paid positions.

He has thought efficiency for fifty years; he has taught it for forty years; during twenty years he slowly collected data for this course.

Efficiency is the modern worker of miracles. It turns failure into success—it takes the man from the tail end of his profession and puts him on the top—it gives health to the sick man—it gives leisure to the harried, over-worked man—it gives security to the worried man. Efficiency will make a success of the business you are in now. You don't have to change your profession or your business. Efficiency simply is the shortest, best, simplest way to do the things you are doing now. No matter who you are, Efficiency is the thing for you. One-third of our students are executives and owners, one-sixth are professional men, the others, accountants, salesmen, engineers and men in every walk of life. Many are women, housekeepers.

It has been my puzzle to know why men who with ordinary schooling, are so successful financially, — The Course in Personal Efficiency discloses the secret.
JOHN D. McEWEN.

I was unable to keep up with my work. I was losing ground. I cut out the overtime before I had gone through the third lesson, and now I am doing a great deal more than formerly and still quit before "Quitting time." This I never used to do.
E. Q. CANNON.

I borrowed the money to subscribe for the course. From the first lesson I have taken a new lease of life. In spite of the adverse conditions caused by the war, I am doing very well indeed.
W. H. KELLER.

Long ago, before the course was half through, it paid for itself in lump sums, in increased salary and in mental, and physical improvement.
GEO. T. JENKINS.

I was breaking down. It seemed almost foolish for one in my financial and physical condition to invest money in a course that would mean more work; but I was desperate.
Within 2 months I was catching up in work, my bank account was growing larger. My health was rapidly regaining its normal state.
GEO. D. HALSEY.

## FREE — This Book

**20 Chapters, In Colors, Illustrated**

Send for this book. It contains the answer to the ever-present question of "Where is the Money Coming From?" Some of the chapters: What is Efficiency? For Whom is Efficiency? How are You Taught Efficiency? Are You Ear-minded or Eye-minded? Most Failures are Due to Guess-work. You Use Only Half Your Power. To What Do Some Men Owe Their Success? Health Culture, Personal Finances. Mr. Emerson's Message to You.

Sending this coupon costs you nothing, will put you on the road to leisure and success. It will give you a wider view of your business. This course is not an expense. It isn't even an investment for future returns. It pays for itself with the first page of the first lesson.

## NEW BOOKS, ETC.

"Practical Engineer" Electrical Pocket Book and Diary for 1920. London: The Technical Publishing Co., Ltd. 18mo.; 755 pp.; illustrated.

This familiar British annual comes of age with this issue, which maintains the usual practical balance between the comprehensive and the compact. Great Britain has recently sought to relieve inventors by a new Patent Act; its main provisions will be found here, with many other up-to-date additions and revisions. The buyers' guide in French, Spanish and Russian is a markworthy and helpful section of the little book.

Motionism. By E. J. McCarthy Morris, F.R.C.S. London: The Caxton Press, Ltd. 12mo.; 130 pp.

"Motionism" is an attempt to explain the visible world, and to furnish an acceptable foundation for a universal religion or ethical philosophy, by taking as starting-point a simple experiment from which the author arrives at a "trinity" of matter, mind and motion.

Silver. Its Intimate Association with the Daily Life of Man. By Benjamin White. New York: Isaac Pitman and Sons.

The author, a British economist and statistician, sets before us the story of silver, from mining, extraction and marketing to its consumption by the arts and industries and its use as currency. He pays a compliment to the annual report of the Director of the United States Mint as "the principal, one might almost say the only, authority upon world statistics." The interesting little work quotes freely from this source.

Acids, Alkalis and Salts. By G. H. J. Adlam, M.A., B.Sc. New York: Isaac Pitman and Sons. 8vo.; 112 pp.; illustrated.

While this handy little book devotes some space to theoretical considerations that initiate the student into the study of chemistry, its aim and end is rather instruction in the commercial and domestic importance and uses of these wonder-working substances. Its facts are simply and interestingly put before the reader, and form a very good introduction to further study.

Employment Psychology. The Application of Scientific Methods to the Selection, Training and Grading of Employees. By Henry C. Link, Ph.D. New York: The Macmillan Company, 1919. 8vo.; 440 pp.; forms.

Psychology as applied to industry has now reached a point where methods and results may be beneficially compared and judged. The employer wants to select the fittest applicant, and to bring him to maximum efficiency by the quickest and soundest methods. The author of this work avails himself of the experience of both psychologists and industrial experts. He takes a representative industry and gives an impartial account of tests under working conditions; guides the reader to a practical investigation of such tests; and enables him to put the right tests into operation. Anyone considering the abolition of old, happy-go-lucky methods will appreciate the concrete help the volume extends.

Silvanus Phillips Thompson, D.Sc., LL.D., F.R.S. By Jane Smeal Thompson and Helen G. Thompson, B.Sc. New York: E. P. Dutton and Company, 1920. 8vo.; 372 pp.; illustrated.

This biography portrays the scientist through his work; it is a charmingly written and inspiring record of a busy and useful life. As lecturer, writer, discoverer and inventor, Thompson contributed largely to electrical science, wrote biographies of Faraday and Kelvin, delved into light and radiation, and optics and illumination, and received, if somewhat tardily, recognition in a long list of honors and degrees. Thompson had also a delightfully human side; he wrote poetry, painted pictures, and took a huge enjoyment in family life. His many-sidedness is faithfully reflected in the biography, and makes it absorbing reading for all, whether scientists or not.

British Airships. Past, Present and Future. By George Whale (Late Major, R.A.F.). New York: John Lane Company, 1919. 12mo.; 244 pp.; illustrated.

In 1914 the British airship was rather a joke. The war period saw the British airship fleet the largest in the world; it cruised 89,000 hours and covered two and a quarter million miles. Major Whale follows this remarkable development step by step, using 24 plates to illustrate army and navy types. The airship's sterling work in the war is crisply reviewed, and the reader is enabled to talk intelligently of rigids and non-rigids, gross and net lift, and the operation of ballonets. Some of the prophecies of the final chapter, notably the crossing of the Atlantic, have already become historical facts.

The Roman Civilization. By A. F. Giles, M.A. London: T. C. and E. C. Jack, Ltd. 8vo.; 160 pp.; illustrated.

This is the fourth volume of a series called "Through the Eye," in which the text, though fairly copious, is subordinate to the pictures, and omits sujects that do not lend themselves to pictorial treatment. This method holds the attention, and gives a fresh impression of social, economic and political conditions in old Rome. Religion, militarism, art and industry are all reflected in the beautiful plates. The text is for the most part taken from another volume by the same authority, but has been rearranged and thoroughly revised.

The English of Commerce. By John B. Opdycke. New York: Charles Scribner's Sons, 1920. 8vo.; 435 pp.; illustrated.

Business English is an art in itself; like literary English, it must be correct and attractive, but in addition it must possess a dynamic force that persuades to action. Many of its terms, too, are peculiarly its own; these are ignored in the schools. Mr. Opdycke's work applies words and sentences to definite ends, teaches how to write convincing human letters in place of the atrocities of the past, is particularly helpful in advertising and face-to-face salesmanship, and will make itself invaluable to all who would energize their business language. Every page abounds in sound principles and the best practise.

Business Law. By Thomas Conyngton. New York: The Ronald Press Company, 1920. 2 vol.; 8vo.; 870 pp.

With laws pouring in a steady stream from our federal, state and municipal law manufactories, it becomes increasingly difficult for the business man to avoid the *verboten*, however honest his intentions. Still, there are guiding principles and general rules a knowledge of which will help the man of affairs immensely. These principles a lawyer who is himself schooled in practical business sets forth in this well-ordered working manual. It covers in the form of an edifying reading course all the main divisions of business—contracts, sales, insurance, employment, patents and trademarks, taxation, and many other points, providing the business man with an authoritative basis upon which to make all decisions involving business and property.

Paints and Varnishes. By Arthur Seymour Jennings, F.I.B.D. New York: Isaac Pitman and Sons. 12mo.; 108 pp.; illustrated.

This helpful manual of condensed information treats of paints and varnishes with particular reference to their properties and uses. Property owners and architects, as well as painters, will find here the characteristics that determine quality, the quantity necessary to cover a given surface, and the probable durability of the coating, with descriptions of paint-making machinery and the latest spraying apparatus. Whitewashes, distempers and enamels are included in the discussion.

Agricultural Prices. By Henry A. Wallace. Des Moines, Iowa: Wallace Publishing Company, 1920. 8vo.; 224 pp.; illustrated.

Innumerable persons are directly concerned with farm product prices. This work will be useful to all such, and more particularly to agricultural students, corn-belt farmers, and farm organizations. The reader will gain from it a precise knowledge of price-making factors and forces; to understand a force is to be in a position to cope with it intelligently; and in the case in point there is hope that a wider understanding may result in the avoidance of costly mistakes, fair compensation, and less violent fluctuations. The work is adaptable to college courses, and stresses the application of statistical laws.

New York Charities Directory, 1920. By Lina D. Miller. New York: Charity Organization Society. 8vo.; 417 pp.

Social service is carried on in so many different ways, by so many different organizations, that this Directory of Greater New York's activities is absolutely necessary to those who need to trace its ramifications. The 1920 edition provides easy approach, not only to the institutions whose names are known, but to all organizations of any desired class, of any required borough, and also to the individuals prominent in the administration of the various efforts toward health and rehabilitation. Its scope is broad, and includes religious, educational, medical, industrial and civic work.

ONE hundred thousand miles is ordinary performance for a White Truck. Some have seen half a million miles of active service. Many have rounded out 200,000 and 300,000 miles, still doing a full day's work.

Spread over such mileages, the purchase price of a White Truck is a small item indeed in the cost of transportation. Earning power continues long after the investment is written off the books.

Following is a list of owners' records which have come to our attention. There are probably many others. The list includes the names of owners and the number of their White Trucks that have gone 100,000 miles and more.

# TRUCKS

THE SCIENTIFIC AMERICAN, November 13, 1920. Volume 123, Number 20. Published weekly by Scientific American Publishing Company at 233 Broadway, New York, N. Y. Subscription price, $6.00 per year.
Entered as second-class matter June 18, 1879, at the post office at New York, N. Y., under the act of March 3, 1879.

# Which of these salesmen will get in?

*ANSWERING this question, a prominent buyer said, "Nowadays I must divide salesmen into two classes, first, those who call to get something, and second, those who come to contribute something. It is hard to turn away the latter kind who bring information and service helpful to me."*

The word "Salesmanship" does not fully express the work that such men do. Their function is bigger than that.

The salesman who can contribute to the cause of fire prevention or the reduction of up-keep cost by skillful advice as to a properly constructed Johns-Manville Asbestos Roof is not a salesman only, for his work is more than commercial—it is economic.

The Johns-Manville man who can show a saving:—maybe thousands of dollars in fuel; a reduction in plant maintenance, or by preventing a shut down on a much needed boiler, makes the order he gets merely an incident to a greater purpose.

So, Johns-Manville waste killers have a real job. They must combine with a willingness to serve a wide experience and a thorough knowledge of those Johns-Manville materials which promote the cause of conservation everywhere by cutting fuel and power losses, preventing property losses and saving time and money.

It may be that some day a Johns-Manville man's card will come to your desk. Use the opportunity to let him show you how he can help you.

Let him tell you something of how his company serves and protects its customers. Let him explain how it has insured the quality of its products by the highest manufacturing standards, rigidly maintained, how it believes in its men and, because to you they are Johns-Manville, how it expects them to live up to its standards in all they do.

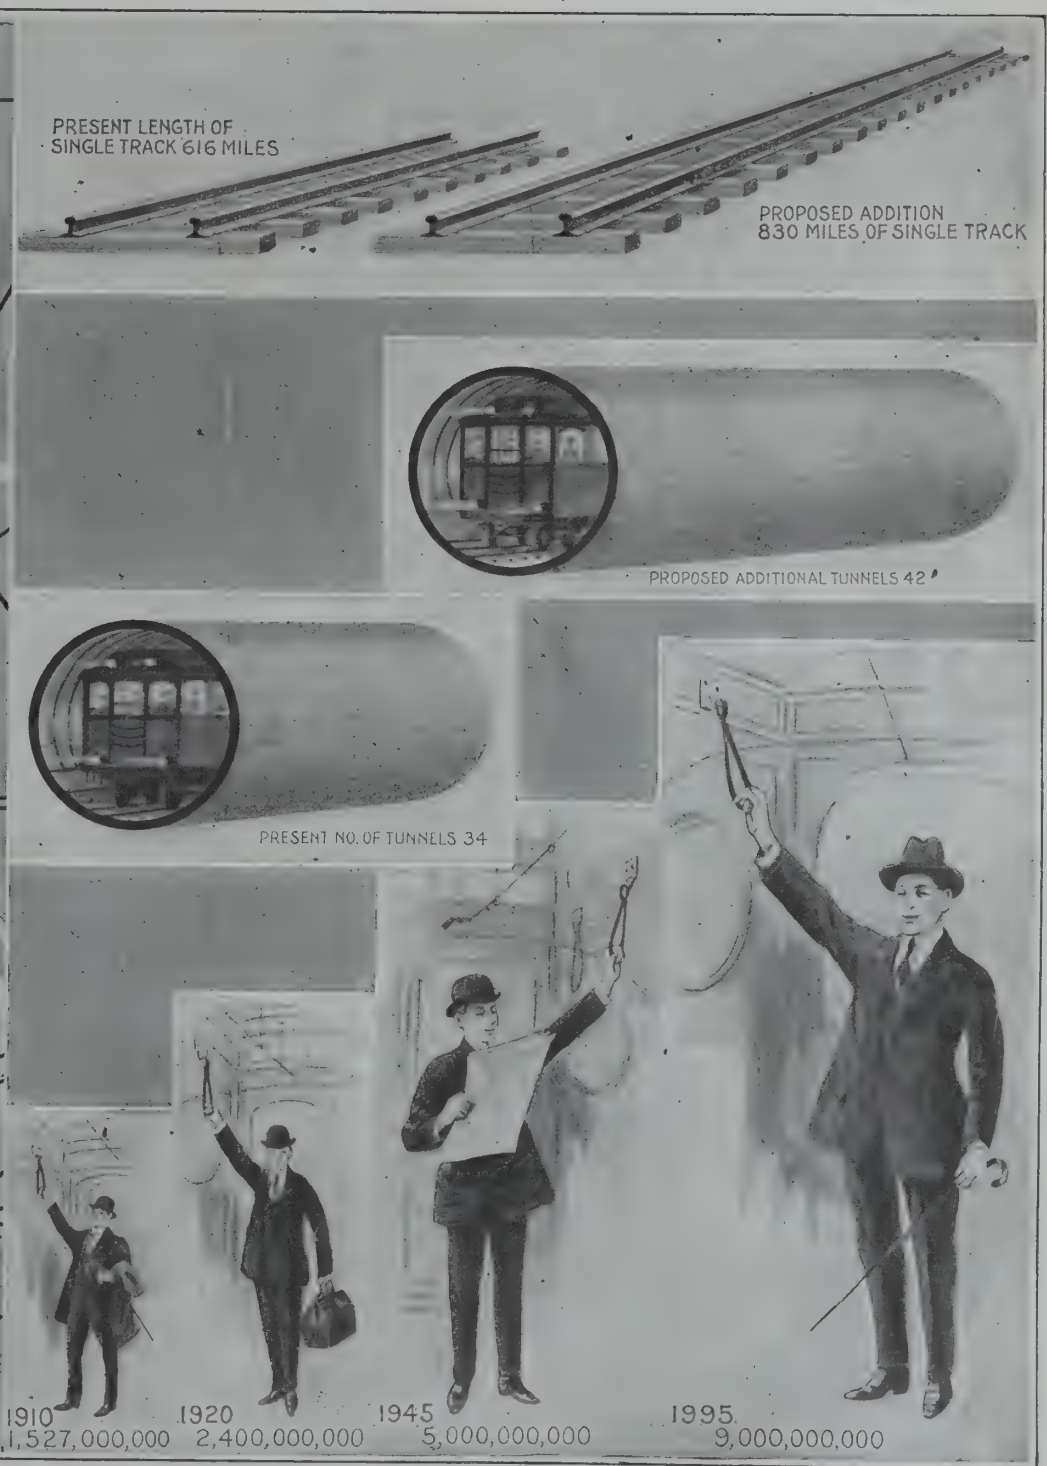
THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME CXXIII. NUMBER 20 ] NEW YORK, NOVEMBER 13, 1920 [ 15 CENTS A COPY 20 CENTS IN CANADA



Map of lower Manhattan, showing in black lines the new subways which must be progressively built, in addition to the existing subways (not shown on map) if we are to keep pace with the growth of travel during the next 75 years. The construction to cover the needs of the next 25 years includes four tracks of a double deck, 8-track subway under Eighth Avenue, four tracks of a 6-track subway under Madison Avenue, crosstown moving platforms under 14th, 42d and 57th Streets, and additional tunnels under the East River at Ann Street, Maiden Lane, The Battery and 23d Street and the Narrows. The trunk lines on Third, Ninth and Tenth Avenues, with their branches, and the additional tunnels to Brooklyn, Staten Island and Jersey City, with numerous extensions to the city line, will be completed in the period 1945 to 1995. The drawings to the right show the estimated future subway travel, in passengers per year, and the tracks and tunnels that must be built to meet it during the next 75 years.

**ADDITIONAL RAPID TRANSIT LINES REQUIRED TO CARRY THE POPULATION OF NEW YORK IN 1995.**—(See page 500)

## In Justice to the War Department

IN considering the storm of criticism which broke upon the War Department on the eve of the recent election, the attitude of the SCIENTIFIC AMERICAN is of course strictly non-partisan. The subject interests us only on its technical side, and for the reason that during the war and at the armistice we dealt very freely with the matter of military equipment.

The charge that in the raising of our huge army and providing it with adequate equipment the Department was guilty of wholesale extravagance and wastefulness, we do not consider to be well-founded. Had our authorities possessed the prophetic vision of a Hebraic seer; had they been able to predict that on November 11th of the year following that upon which we declared war, the great German army would fall like a pack of cards; the scale upon which we enlisted our young men and provided the clothing, food, rifles, machine guns, field guns, heavy artillery, powder supplies and all the equipment and impedimenta of war, would have been extravagant and wasteful to the *nth* degree.

But lacking such prophetic vision, the War Department had to base its estimates upon the military conditions as they existed in the spring of 1917, when the enemy was at the very crest of his military achievement. What were those conditions? Servia was under his heel; Roumania, too. Russia had crumbled, and the whole defensive line of the Central Powers was intact and apparently unbreakable. Moreover, the most optimistic of the high commanding officers of our allies were agreed that the war would last through the season of 1919; while there were not a few who believed that the final blow could not be struck before 1920.

Are we now to blame the War Department because it acted in accordance with the existing conditions and planned for recruitment and supplies upon a scale proportionate to the immensity of the undertaking? And yet this is exactly what the recent critics of the War Department have been doing; and, in our opinion, the whole proceeding has been as unjust as it has been ungenerous.

True it is that at the armistice we found ourselves with enormous plants for the production of guns, powder, et cetera, that were as yet in an incomplete condition. True it is that the fruits of all our preparatory labor were only then beginning to reach the western front in quantity. But true it is, also, that had the war stretched on into 1919, our rapidly increasing armies at the front would have been supplied with every war necessity upon such a generous scale that the surplus which existed at the armistice would have been fully consumed.

It is unquestionable that the enormous extent of our preparations for 1919 went a long way toward causing the German army to get cold feet in 1918. Moreover, in all fairness, we should remember that the War Department bent its energies so ably to the solution of the sudden emergency presented by the German collapse, that it was able to realize over 4½ billion dollars by the sale of surplus supplies and the settling of claims.

No. The outstanding lesson of this whole matter is that those among us, who, like General Wood, worked day in and day out to urge upon Congress the necessity for preparedness, have received in this matter a tremendous endorsement of their policy. The War Department made mistakes, of course. Who does not? But had their program of 1917 been absolutely flawless, the 25 billions of dollars' indebtedness that is upon us today would have been but slightly reduced. Had we on the other hand but listened to the voice of Wood in 1914 and 1915, the Germans would have asked for an armistice at least one and possibly two years sooner than they did, and it is certain that our present war expenses and those of our allies would have been cut in half.

## A Stupendous Rapid-Transit Problem

UNQUESTIONABLY, the most pressing engineering problem of the day in New York City is to provide adequate rapid transit facilities, not alone for the present population but for the teeming millions which are being added to the city at a rate which steadily accelerates year by year.

The ideal topography for meeting such conditions would be that in which the various lines of travel were able to radiate in all directions freely and without any physical obstacles to prevent the construction of subways, elevated roads and street car lines. Instances of these conditions are to be found in London, Paris and Berlin, where the rivers upon which the cities are situated are so narrow as to afford but slight obstacles to the construction of bridges and tunnels. The business center of New York, however, is situated on the lower half of Manhattan Island, which, with an average width of less than two miles, extends north and south for a distance of ten miles and is hemmed in by the deep and broad East and North Rivers, the former necessitating bridges with a clear span of 1,500 to 1,600 feet and the latter calling for a clear span of the unprecedented length of 3,000 feet and over.

Modern developments in civil and electrical engineering have made possible the crossing of these natural obstacles by the alternative method of tunneling. The Greathead shield and electric traction have brought the cost of tunnel construction and operation within practicable limits, although the crossing by bridge still remains, and always will, a far more economical method when compared on the basis of cost per single track; and it has, of course, the advantage of being a more pleasant mode of travel from the viewpoint of the passenger.

The configuration of Manhattan, which is today and always will be the commercial hub of our great city, greatly complicates the problem of providing rapid transit service, for the reason that the natural flow of traffic is north and south through the avenues, and in the early years of the history of transportation, we find that the bulk of the travel moved in these directions. Even in the future, when the North and East Rivers shall have been crossed by a multiplicity of bridges and tunnels, the city will be at a disadvantage as compared with those having a radial system of distribution, because of the fact that rapid transit to the south and southwest is hindered by the broad waters of New York Bay. In a city like Paris, having a free radial distribution, the territory served increases as the square of the distance from the city center, whereas in Manhattan it increases directly as the distance.

We invite the citizens of New York to make a careful study of the present and future problem of transportation in their city as portrayed in the map and diagrams on the front page of this issue and as described in the article on page 500. The engineers and the Transit Construction Commission are to be congratulated upon their foresight in making such a comprehensive study of this problem and presenting it for public consideration. Easy it is to be wise after the event; but, as the history of municipal improvements has shown, it is very difficult to teach the public wisdom before the event—the wisdom of judicious foresight and preparation. No one can study the statistics which are here presented without realizing that unless the city fathers hasten the completion of the present subways, and act upon the proposed plans to take care of the increase in travel for the next twenty-five years, we shall sooner or later, and rather sooner than later, find ourselves confronted with a congestion of travel which would be little short of a public calamity.

In justification of the above warning, and having in mind the frightful jam which occurs in the rush hours even today, we invite attention to the fact that from 1910 to 1920 rapid transit travel on all lines increased, roughly, from 1½ billion passengers per year to about 2½ billion, and that within the next twenty-five years these figures will have doubled to 5 billion passengers, and fifty years later or by the end of the century, there will be an annual travel of some 9 billion passengers.

## The Naval Experimental Laboratory

THE new naval laboratory for which Congress has appropriated $2,000,000, owes its inception to the Naval Consulting Board. It will be remembered that one of the first recommendations of this body was the building of a large and thoroughly equipped laboratory in which promising inventions could be investigated and rejected or developed, as the case might be, on a scale and with a completeness which existing conditions in the Navy Department rendered impossible. In furtherance of this scheme a committee of the Board, composed of men who were expert in laboratory work, was appointed to formulate a general plane and select a site. For various reasons, they reported to the Board in favor of Annapolis; but in the discussion which followed some diversity of opinion developed, notably in the case of Mr. Edison, who was strongly in favor of New York.

This took place after 1914 and before our entrance into the European war. The rush of our preparation for that great conflict and the multiplicity of larger problems that developed, coupled with the fact that there was an offer to the Government of many private and well-appointed laboratories, caused the subject to be dropped for the time being. It should be mentioned, however, that the choice of Annapolis was favored by naval officers, who pointed out that the Government had already established an experimental laboratory at that location, which had cost about $600,000, and that there was ample land for expansion of the plant. Also it was urged very strongly that the work of the laboratory be coördinated with that of the Naval Academy, and particularly with the work of the postgraduate school, which, by the way, has been opened up again since the war, and is to be greatly expanded. The point was made that an adequate experimental and research laboratory at the naval college would enable the student officers to do special research work, and that the experts of the laboratory might be employed as lecturers at the postgraduate school. In the minds of many naval officers this was the strongest of all considerations.

However, the laboratory committee, after giving due wieght to the opinion of naval officers, has finally decided against Annapolis, and in favor of a site at Bellevue, a naval reservation near Glesboro Point on the Potomac and lying in the District of Columbia. The site is opposite and about one mile distant from the War College at Washington.

The principal considerations which led to the choice of the Washington site are first, the desirability of locating the laboratory as near as possible to the Bureau of Standards, with which institution the work of the laboratory must necessarily be carried on in close and continual coöperation. Secondly, it was considered desirable that the laboratory should be built within easy reach of the various naval bureaus, particularly those of Construction and Repair, Steam Engineering and Ordnance. Another consideration was that of assuring the future finances of the institution, which would have to come in the form of appropriations from Congress. Laboratory work and plant is frequently difficult to explain to the lay mind. If the laboratory were located within half an hour's automobile ride from the Capitol, it would be possible to take the committee down and show them work which was being done and explain on the spot why the requisite appropriations were necessary. A final reason and alas, perhaps the most important of all, was that by locating the laboratory in the District of Columbia, whose residents have no vote, it would insure that the financial prosperity of the institution would not depend upon those familiar tactics known under the name of "log-rolling." If Congressmen had no particular political object to further by giving or withholding appropriations, it was realized that the prospects of the claims of the laboratory obtaining just and unbiased consideration would be greatly enhanced.

## Engineering

**Nicaragua's Highways,** according to the American Consul, are the rivers and lagoons. There is not a mile of road anywhere in the Bluefields district. However, the fact that the Nicaraguan Government appropriated $250,000 out of the national revenues of the Republic for the construction of certain automobile highways seems to indicate that the beginnings of a definite plan for such construction have been made. During 1919 three automobile roads approximating 200 miles were under construction, as follows: From Porto Dias to La Libertad, from Managua to Matagalpa, and from Montagalpa to the Pacific Coast.

**Cement-Lined Service Pipes.**—Among other economies introduced in the waterworks department of Lynn, Mass., whereby that town was able to offset advances in prices and wages and maintain the water supply at the old figure, was the substitution of cement-lined pipe for an expensive type of lined pipe which did not stand up very satisfactorily with Lynn water. To prevent the breaking of the lining with ordinary pipe-cutters, all pipe was cut in the shop to fit the requirements by the use of a metal cutting machine, which, on a test with a single blade, cut 140 ⅛-inch disks from a piece of 1-inch lined pipe without breaking the cement. To prevent exposed threads in connections, malleable iron countersunk fittings are used, which are lined in the shop with lead, leaving only six threads unlined. When this lining comes in contact with the cement lining of the pipe it makes a snug fit without danger of crushing the latter.

**The Hudson Bay Railway.**—Agitation is being renewed in western Canada for the resumption of work on the Hudson Bay Railway, now needing only 92 miles of construction to complete a short cut across the narrow end of the globe, reducing the distance from Calgary to Liverpool by about 1,350 miles. The deep-water development of the harbor at Port Nelson, consisting of an artificially constructed island, situated near the outer edge of the tidal flats, about two-thirds of a mile from shore, connected with the mainland by a bridge of seventeen spans, has created some opposition to those who favored Port Churchill for the railway terminus. The island as built is now one-half mile in length and enclosed on all but the deep-water face by timber crib retaining works, and the interior has been partly filled with material dredged from the site of the deep-water wharves and channel. The work was greatly interfered with on account of the war.

**The Use of Compressed Gas.**—It appears as though all progressive countries are making extensive use of compressed gas for various purposes. Argentine Republic, for instance, is manufacturing and compressing gas locally and the output of the factories is used by the entire country. The machinery for its manufacture was originally imported from France and Germany. Compressed gases are used in Canada, in connection with industrial establishments and hospitals. Importation is made in large cylinders, the gas being repumped into smaller ones for distribution. The gases come from the United States. In India compressed gases are generally used by the principal engineering, shipping, dock, and railway concerns for welding and cutting metal; also in many of the hospitals. The gases are of local manufacture. In Sweden compressed gases are being used extensively for welding. Shipyards and large shops produce the gas in their own plants instead of buying cylinders with compressed gas. Machinery for the production of compressed gas was formerly obtained in Germany and France, but Sweden now supplies its own markets.

**Building Blocks from Clinkers.**—A local enterprise of Brest, France, which suspended operation during the war has recommended the production of building blocks that are gaining widespread usage in the Brest district in certain kinds of building construction. The blocks are made in molds as are cement building blocks in the United States. The materials used are sand, lime, and cement, with a base of crushed coal clinkers. The lower grade of blocks also contain some coal cinders. These blocks are made in several sizes. The size 10 by 20 by 6 inches sells for 237 francs per hundred blocks. The clinker building blocks are particularly used in pavements, walls, floors of cellars, warehouses, stables, garages, rough buildings and small residences. The blocks have the advantage over brick for building material in that they are cheaper and facilitate quick construction. They take plaster on the interior and stucco on the exterior where it is desirable in buildings. However, the outstanding advantage of the clinker block over the brick in the Brest district is the capacity of the former to withstand the great humidity of the climate that causes brick walls to drip water in the interior of the houses.

## Science

**Dust Hazard in Wet Grinding.**—The Public Health Service has published a report by Messrs. Winslow and Greenburg on the dust content of the air in the grinding rooms of a large Connecticut factory, where wet grinding is the rule. This process is generally supposed to be relatively harmless to the workman. In the case examined, however, the air was found to contain, on an average, 15,800,000, and in one sample 50,000,000 particles, mostly 1 or 2 microns in diameter, per cubic foot. The dangerous condition thus indicated is confirmed by the fact that the tuberculosis death rate among the operatives is ten times that of the general population. In order to facilitate rapid work, the grinders are tempted to cut down the amount of water supplied to the wheel, and in grinding a heavy object like an ax upon a wheel of soft natural sandstone the worker presses so heavily upon the wheel that the superficial layer of water is pushed back behind the ax and the outer surface of moist stone is ground off, exposing a dry surface, which, in its turn, is abraded and discharged as atmospheric dust. In view of these conditions, it would be a benefit to the workers to substitute dry grinding, with an efficient exhaust system.

**How Do Raindrops Form?**—The stereotyped explanation of the formation of raindrops contains some rather striking fallacies. It is assumed that when air is cooled below the dew-point condensation occurs on the nuclei present; that the larger droplets, owing to their lesser vapor tension, grow at the expense of the smaller; and that the larger and more rapidly falling drops coalesce with others on their downward path to form full-sized raindrops. Dr. W. J. Humphreys, who dealt with this subject at the last meeting of the American Physical Society, pointed out that the number of condensation nuclei in a given volume of air is ordinarily so great that the amount of moisture present could not form drops as large as raindrops around them. In fact, the available space would not hold as many raindrops as there are nuclei. It is true that the larger drops do grow at the expense of the smaller, but according to theory, at a rate far too slow to be effective in the process of rain production. Lastly, even if a droplet should fall quite through a cloud layer and actually coalesce with all the particles in its path, the chance of its thus becoming a full-sized raindrop would be very small. Dr. Humphreys explains rain formation thus: Humid air ascends and forms cloud droplets on the nuclei present as soon as the air cools below the dew-point. The drops in the lower part of the cloud thus formed filter out most of the nuclei from the air ascending still higher. Thus at upper levels there are so few nuclei that a drop of "falling" size can form around each of them. These drops doubtless often grow larger through coalescence with other drops during their fall. The last process is facilitated by the electric charge which the drops usually have.

**The Uses of Helium.**—The production of helium on an extensive scale which began during the war, when it was proposed to use this gas for filling balloons and dirigibles, has led to considerable discussion as to other ways in which helium can be used. Prof. J. C. McLennan deals at length with this question in a lecture, published in *Nature*. It appears, in the first place, that if helium is used for filling airships the supply from the British Empire would be far from adequate for the British air fleet. One way of economizing it, would be to use it only in compartments adjacent to the engines. As to various industrial uses, it may be used as a filling for thermionic amplifying valves of the ionization type; also for filling tungsten incandescent lamps, especially for signal purposes where rapid dimming is essential, and for producing gas arc lamps in which tungsten terminals are used. Some objections to these uses are pointed out. Nutting has shown that Geissler tubes filled with helium are very suitable, under certain conditions, for light standards in spectrophotometry. Helium is also invaluable in spectroscopy, and for various other laboratory uses. Elihu Thomson has suggested that if divers were supplied with a mixture of oxygen and helium, the rate of expulsion of carbon dioxide from the lungs might be increased, and thus the period of submergence might be considerably lengthened. The widest application of helium, however, appears to be in the field of low temperature research, as liquid helium—and perhaps eventually solid helium—enables one to reach the lowest temperatures attainable by any means. A point of special importance to which Professor McLennan calls attention is that the supplies of natural gas from which helium can be extracted are being rapidly used up; hence it might be well to store a supply of this gas for use in years to come.

## Industrial Efficiency

**Shoes from Mud Shark Skins.**—Fancy footwear and other novelties are to be manufactured by a company of Victoria, B. C., from the skins of mud sharks. Operations are now under way. The company has been granted an exclusive license to fish for mud sharks in the Gulf of Georgia.

**France's Steel Industry.**—Steel manufacturers and merchants throughout France are all of the some opinion—that the present demand in France for foreign steel products, including plates, sheets, beams, sections, channels, wire rods, tubes, and angles for railway car construction will continue for at least a year. No home-made plate is available for the independent shipbuilding plants. Such ship plate as is now produced passes directly from the mills to shipyards in which the mills are financially interested. It is said that by this month only 25 per cent of the mills are operating, due to the shortage of materials.

**Paper Pulp from Congo.**—Papyrus, which grows in great abundance near Elizabethville, in the Belgian Congo, principally along the lower Lualaba, near the lakes of Kabuli, Sjemba, Kisali, and Neaga, is to be exploited by a large company which has been granted a concession. It is planned to establish near the river a large plant, costing two and a half million francs, which will have an initial production of 20,000 tons of pulp. The material for this factory is to be sought among the Belgian, and, if necessary, allied manufacturers. The papyrus of the Congo has shown on analysis to contain 37.8 per cent cellulose. After research and experiments, a process was discovered for bleaching the plant.

**The Pigment Deposits.**—The discovery of an extensive deposit of ocher and sienna at no great distance from the surface and within 30 miles of Adelaide, South Australia, has attracted much local interest, particularly in view of the abnormally high price of imported paint pigments. Though regarded primarily as a mining proposition, the discovery is important in a manufacturing sense. During the years of war several new paint works were established in Australia, but the promoters were handicapped to some extent by the necessity of importing most of the requisite raw materials. This new find of ocher and sienna therefore extends the possibilities of the paint industry and should render it largely independent of overseas supplies of the basic pigments.

**Peat as Locomotive Fuel.**—Interesting trials to test the possibilities of peat as fuel for locomotives have been in progress for some months on several railroads in Sweden. The reports so far show favorable results. One privately owned railroad in southern Sweden, 256 miles in length, has found peat so practical for steam purposes that the management believes the road can dispense entirely with coal. The State railways have likewise been testing peat for steam purposes, with good results, and have on a limited scale adopted it for fuel. For some years the State railways have been operating a factory for the production of peat powder, which is said to be an excellent fuel. In Sweden, where there are 10,000,000 acres of peat bogs, with an average depth of 6.6 feet, the substitution of peat for coal would add enormously to the national wealth. Every acre of peat bog yields nearly 1,000 tons of prepared peat.

**America's Option on German Chemical Drugs.**—The Reparation Commission has offered to the United States Government the right to participate in the purchase of certain chemical drugs from stocks impounded in Germany as well as from the subsequent production of German manufacturers, rendered available to the Commission by the Treaty of Versailles. From the records in possession of the War Trade Board Section it would appear that practically all these chemical drugs are now being manufactured in the United States and are available to the American consumer on reasonable terms as to price, quality, and production. Reliable reports indicate that the domestic product is equal to the German in quality; that the average price is substantially the same as that asked by the German manufacturers for stocks of current production; and that these drugs are manufactured in this country in quantity sufficient to meet all indicated domestic demand. The foregoing covers not only synthetic organics of commerce, but likewise practically all of the German patented products. For this reason this Government does not feel it advisable to take active steps to place upon the market foreign-made drugs which would compete with those of domestic manufacture, and, therefore, will not exercise its option upon impounded stocks of chemical drugs of German manufacture or upon stocks of chemical drugs manufactured during the months January, 1920, to June, 1920, inclusive.

# The State and the Farmer

## Successful Development of the California Land Settlement Scheme

By H. A. Crafts

Levelling and checking land for California's experiment in directed semi-cooperative farming

*THE United States, as is clearly shown by so much of the 1920 census returns as has been made public, still suffers from the tendency of the rural population to gravitate toward the city. Ways and means of meeting this situation and insuring that we shall have left enough producers of food to feed the nation are becoming more essential every year. One way is to make it easier for the small farmer to acquire title to the land which he works, and to aid him in the successful cultivation of that land. This sounds like the cooperative schemes which have failed with such singular unanimity wherever they have been tried; that it does not necessarily involve the weak elements leading toward such failures must be concluded from the great success which has attended the California Land Settlement scheme. What this is and how it has worked Mr. Crafts tells us in this story.*—THE EDITOR.

THE California State Land Settlement Scheme at Durham, Butte County, was launched in 1918, and is the first settlement of the kind to be established in the United States.

A tract of 6,219 acres of farm land purchased by the State was subdivided into small farms, ranging in size from two to one hundred and fifty acres.

The spirit in which the colony was started is best indicated by the enabling act adopted by the California State Legislature in 1917, which contains the following clause:

"The Legislature believes that land settlement is a problem of great importance to the welfare of all the people of the State of California, and for that reason through this particular act endeavors to improve the general economic and social conditions of agricultural settlers within the State, and of the people of the State in general."

By provisions of this act the Legislature appropriated the sum of $260,000, of which $250,000 was constituted a revolving fund for the purpose of purchasing and improving farm lands to be sold in turn to bona fide settlers.

The land purchased for this first settlement was a part of the old Senator Leland Stanford estate and with the exception of about one thousand acres is composed of deep, rich alluvial land, lying along the shores of Butte Creek.

Under two allotments and sale in 1918 the entire tract was quickly disposed of, and provided beautiful and productive homes for 120 families, including 200 children.

The enterprise is not of an eleemosynary character, but one designed to help real farmers, possessing real capital, to accomplish better results in the way of practical agriculture. The State Land Settlement Board, a body consisting of five members appointed by the Governor of the State, exercised great pains in allotting the settlement-farms to desirable purchasers. Due consideration was taken of moral character, practical farm experience and financial standing, with a view of welding the settlement into a permanent and prosperous community.

The cost of the land to the Board was $100 per acre for that portion which was susceptible of irrigation, and $10 per acre for that portion that was non-irrigable. Of the latter there were only about 700 acres. This land in turn was sold to settlers at an average price of $150 per acre, and the total price of farm units ranged from $3,600 to $15,000.

The terms of sale to settlers included a cash payment of five per cent of the purchase price, with deferred payments extending over a period of forty years, at five per cent interest. Loans were extended for farm houses and other permanent improvements up to sixty per cent of their cost with twenty years for repayment. No loan for this purpose was made above $3,000.

Very wisely the State Land Settlement Board took cognizance of the vexed question of farm labor and provided for the allotment of two-acre tracts for this class of settlers. These lots were eagerly taken. The initial payment on each lot was less than $20, and deferred payments were arranged on the same basis as those made to farm settlers.

This arrangement was made with a double purpose—that of providing the settlement with a permanent supply of farm help and also of raising the standard of general farm help to a higher level.

The farm laborers of the settlement were enabled to earn from $2.50 to $3.50 per day, with board, or $4.50 without board. Carpenters were paid $5.25 per day of eight hours and were enabled to improve their allotments outside of the working hours.

These settlement farm laborers have the option of either working inside or outside of the colony. They are permitted, as soon as they are financially competent, to purchase larger farms, and thus become proprietary or employing farmers.

The offices of the California State Land Settlement Board do not cease with the mere buying and selling of this land, leaving the settlers to shift for themselves. The most important work comes after the settlers have selected farms and have begun the arduous task of producing a revenue that will enable them to pay for and equip their new homes.

The Board does all in its power to guide the collective work of the settlement along safe lines, supplying farm advisers, farmstead engineers and other experts to help the good work along. It is the plan of the Board to assist the settlement in welding itself into a successful coöperative community, and to inaugurate a system of the most scientific and up-to-date cultural and administrative methods.

At the very outset the Durham settlers organized a Coöperative Stock Breeders' Association. This was done with the prime object of making the settlement the home of pure-bred live stock. The Board inculcated the idea of uniform selection of breeds so that there should be no untoward mixing of blood.

It was agreed that there should be but one or two breeds of cattle, sheep and hogs in the association. For cattle the Holstein was adopted as the type for dairy stock, and short horns for beef purposes. Duroc Jerseys were selected as the desirable type of hogs, and the Romney Marsh and Rambouillet for the sheep breeds. The executive committee of the Settlement Coöperative Live Stock Association has done nearly all the buying of live stock for the settlers thus simplifying and expediting matters.

Instead of leaving each of the 120 families, composing the settlement, to buy material, find workmen and secure designs for their dwellings and farm buildings the Board took it upon itself to lend a most welcome helping hand. It aided the settlers in their purchase of fencing material, cement, lumber, pipe, etc., in carload lots, thus saving the new farmers much labor trouble and insuring them the best of material at lowest prices.

The plans for the new farm houses and their proper location on the respective farms were worked out with much care by the farmstead engineer under the eye of the farmer and his wife and in coöperation with them. In fact all the important

**The farm woodlots kept many nome fires burning during the fuel shortage of 1918. Will history repeat itself this winter?**

## Winter Fuel from Our Woodlands

**By Arthur L. Dahl**

WHETHER or not there will be a shortage of fuel in our cities and towns this winter will depend upon economic conditions, for congested railroad traffic or another strike in the coal regions will soon result in making many people shiver at the icy blasts of winter, for storage stocks are inadequate almost everywhere. Coal is almost the universal fuel for heating in the home, for oil is only used in the larger apartments, hotels and public buildings providing steam heat. When coal is obtainable, it is undoubtedly the most satisfactory, but when the supply is short our thoughts turn to the fuel of Lincoln's day, and we would give a lot for some of the split rails that helped him earn a meager living.

The farm woodlots during the fuel shortage of 1918 enabled many of the home fires to be kept burning, for thousands of cords were then cut and hauled into nearby towns to take the place of coal, not only for heating the home but often to keep the wheels of industry moving.

Two pounds of seasoned wood have a fuel value equal to one pound of coal, and while different kinds of wood have different fuel values, generally, the greater the dry weight of a non-resinous wood the more heat it will give out when burned. A cord of hickory, oak, beech, birch, maple, locust or cherry, weighing about 4,000 pounds, is equal to one ton of coal. Other species, having less heat value, such as hemlock, red gum, sycamore or shortleaf pine, require a cord and a half to equal a ton of coal. Two cords of such woods as cedar, redwood, poplar, cypress, spruce and white pine are needed to equal the heat value of a ton of coal. Resinous woods have a greater heat value per pound than non-resinous woods, and this increased value varies with the resin content. The available heat value of wood likewise depends upon the amount of moisture present. With green wood much of the heat it is capable of giving is used up in evaporating the water.

Woods have different characteristics in burning, some furnishing a quick, intense heat, while others will burn slowly and evenly. Hickory, of the non-resinous woods, has the highest fuel value per unit volume of wood, and it burns evenly, and holds the heat. Oaks, beech, birch, and maple have somewhat the same qualities, in varying degrees, while the white pines have a relatively low heat value per unit volume, but they ignite readily and give out a quick hot flame, but do not last long. Woods containing lots of resin, although giving an intense heat, give out a large volume of oily black smoke that is often objectionable around the home.

Under normal conditions the United States use about one hundred million cords of wood annually for fuel, of which about 80 per cent is consumed in the rural districts. In spite of the fact that most of our farm woodlands occur in the 17 States making up New England and the Lake States, the farmers and rural population of this section annually use in excess of 18,000,000 tons of coal. If by substituting wood one-quarter less coal could be burned on farms and one-tenth less in villages, the total saving would amount to nearly 3,000,000 tons, or between 65,000 and 70,000 carloads.

Wood, being a bulky and heavy commodity, does not justify shipment for very long distances by rail, but where water transportation is available, considerable cord wood finds its way to the urban markets, for loaded on flats or rafts, a large quantity can be transported at slight expense. Accordingly, along most of our waterways cordwood is one of the articles of commerce, especially when a coal shortage creates an unusual demand for fuel wood.

The development of power farming has resulted in increasing the amount of marketable products from farm woodlots, for in the early days it was necessary to cut up the tree trunks with a hand axe, a slow and arduous undertaking, and few farmers thought the returns were adequate. With the modern tractor, however, to furnish belt power for a small portable saw outfit, it is possible to cut up in a few days a considerable quantity of timber, and farmers owning tractors are more and more getting into the habit of cutting up the dead and down timber and of thinning out their woodlands.

The matter of supplying cordwood from our farms is entirely an economic one. While there are some 143,392,000 acres of woodland on the farms in the

(*Continued on page 508*)

## Forewarnings About Forest Fires

**By G. H. Dacy**

UNCLE SAM, woodsman de luxe, has over 154,000,000 acres of national forest to maintain, improve and guide and guard against fire losses. Destructive conflagrations are the most insidious and insistent foes which the Government has to combat in its efforts to conserve and improve our timber resources. The Federal Forest Service utilizes a unique mechanical display in illustrating pictorially how forest fires emanate. It is not a cinema, although it appears like a motion picture to the spectator. A metal disk five feet in diameter which is driven by a motor is divided into five units separated by vertical partitions, each section consisting of a model of a heavily forested hillside. Each of the five units presents a different cause of forest fire.

Lightning is a fertile source of timberland conflagrations. How lightning causes fire is shown by means of an invisible electric wire which is suspended above the highest trees of one of the models. As the large disk spins around and this particular unit appears before the spectator, an electric spark is made to jump from the invisible wire apparently located in a big, black cloud to one of the trees whence, apparently, the blaze soon spreads over the forest. This effect is accomplished by means of a red electric lamp underneath the hillside, which is practically transparent.

Ranchers and settlers who are extending their areas of cleared land often start bonfires to destroy the debris. Occasionally on a windy day, the fires get beyond control or on the sly shoot out sparks which ignite neighboring woodland. Stupendous losses of valuable timber annually result from such causes. Another segment of the revolving disk pictures such an occurrence, the clearing, dwellings and live stock of the settler being plainly shown in the foreground of the model. Neglected and abandoned camp fires left by careless hunters, fishermen or campers are also prolific in the annual tribute they exact in the way of despoiled woodland. A third reproduction deals with this subject, the camper's tent being shown in the valley with a smouldering fire nearby which gradually blazes and spreads to the neighboring underbrush.

(*Continued on page 508*)

*Left:* Campers often neglect completely to extinguish their fires, which subsequently spread over large areas. *Right:* Sparks from locomotives, logging engines and steam tractors are a fruitful source of unintentional conflagrations.

**Where the forest fires come from and why due care should be exercised at all times**

# Solving the Labor Problem—II

## Man-to-man Contact Between Capital and Labor in Place of the Old Impersonal Relationship

By H. C. Osborn, President, American Multigraph Company

IT seems to me that in our more or less popular discussions of Capital and Labor, we have been satisfied to concern ourselves with details at the sacrifice of fundamentals.

The turmoil between Capital and Labor is not so much ignorance as it is misinformation—and I find one side as misinformed as the other. The trouble seems to be the gradual elimination of the man-to-man contact of a generation ago, replacing it with cold, impersonal employment relationships.

By way of contrast, I recall the stories told me by men who worked for my grandfather. He was the founder of one of Cleveland's big rolling mills and one of the first employers of large groups of men. They tell me that he and his men were real friends; that at noon time he and the men would take their lunch boxes out into the mill yard and seated upon a pile of rails, discuss everything from politics to business. He never knew what labor trouble was. He knew his men, they knew him, and both groups knew all about the business that gave them their living.

Then, when I was finishing my education I became an apprentice machinist in a big Cleveland shop. There I got the other viewpoint. The angle of the man who does not understand the business but who feels himself oppressed by a "System" of which an invisible "Big Boss" is the directing force. To me and the men I worked with, the one aim in life was to get as much as possible for the services rendered. We never knew what the business was all about—and no one in the business seemed to care much whether we found out. There was sort of an atmosphere of "Choosing Sides." We working men had our side and "They" had theirs.

It's that sort of thing that has increased and multiplied to the point that we have now reached. Business has allowed its two factors to become so interested in watching one another that there seem to be few people left to interest themselves in business.

Before we talk about improving conditions, we must recognize the fundamental conditions that are at work and set about bringing a real recognition, on the part of both capital and labor, of the fact that alone they count for nothing—combined, they are useful to themselves only so long as they serve the purpose for which the business was created—rendering some sort of a service to a customer.

From our earliest days we have tried to keep that ideal before ourselves and our men. The first multigraphs built were delivered to Cleveland concerns, and so great was the interest of the men building them that many of the fellows (there were about fifteen of them) had private records of where those multigraphs were and how they were functioning.

We have tried to preserve this spirit as we grew. We have tried to show each man that the part he was working on had some definite service to perform for a customer. By means of talks, charts and pamphlets we have endeavored to show our men the correct relationship between capital and labor, and the part they, as individuals, played in the world of business.

One of these talks, "Modern Business Organization," traced the history of business from the barter age to the present-day corporation. It took the men through the various stages of business and traced the relationship of capital to labor, pointing out their absolute dependence upon each other and their united dependence upon a customer. The result of this was a more united understanding of the part that the worker plays in industry, plus a keener interest in the daily task, because of the realization of the importance of the customer.

Another talk, "Cash to Cash," dealt with the company balance sheet. In this talk we took our annual statement and analyzed it, pointing out the various factors that make up our business and their correct relationship to each other. Overhead, dividends, taxes, surplus, and reserve—all those otherwise unintelligible terms were explained and illustrated by charts and demonstration. Overhead, for instance, was demonstrated to the men by having those whose jobs were part of non-productive labor explain what they did and why it was important. We began with the salesman; had him turn his order over to the clerk in his office, who in turn presented it to the order department man, who then passed his orders around to the various production control units, and so on until the manufacturing order was out in the factory and the man at the machine was at work. By this means we demonstrated the need and importance of the so-called "White Collar" man, and the factory man saw Overhead as an assistant rather than a burden.

All this took time. The course took about a year to give, and covered all possible phases of our business and industrial relations. It was given to a group of about two hundred men who stayed after hours to take the course. We called it our "General Shop Efficiency" course, and out of it grew a demand for the present educational work which covers Foremanship, Mathematics, Shop Practice, Blue Print Reading, Corrective English and Public Speaking, Advertising and Salesmanship, and Business Arithmetic.

*THE very magnitude of modern industry has introduced numerous problems which were unknown to the business minds of a generation ago. Problems of securing raw materials, transportation, distribution, publicity, labor—all of these are peculiar to our present industry. But of all these problems none appears to be so persistent and so difficult to solve as that of labor. How to obtain the proper kind of labor, make it take an interest in the work and ideals of the organization, and prevent it from drifting from place to place with all the losses which such practice entails, is the problem before us. In a previous article we had Mr. Verity, President of the American Rolling Mill Company, explain his company's plan for solving the labor question. This time Mr. Osborn, President of the American Multigraph Company, gives his views and experience on this great question.*—THE EDITOR.

**H. C. Osborn, who calls our attention to the fundamental conditions of the labor problem and how they may be met**

Immediately following our course in "Workingmen's Economics" we began discussing employe representation. Here again charts were used. We showed how the Board of Directors tied the stockholders and the management together, at the same time pointing out how some system of employee representation could be made to give that same contact between management and workers. We let it go at that and appointed several informal committees to investigate existing forms of employee representation and report.

The outcome of it all was the adoption, March 1st, 1919, of the system of employe representation under which we are now working. The system is our own product, made to fit our own particular requirements, but in its fundamentals resembling many of the systems now in successful operation.

We have a Congress of 24 members, elected by the workers. There is a Senate of 14 members holding office by virtue of position, each member being head of some division of our business. There is a Cabinet, the executives of the company, and in case of a total disagreement (something which in a year and a half's experience has not occurred) there is an Arbitration Board.

The Congress is further split into committees. There are fifteen of them as follows: Employment and Discharge; Education and Publication; Health, Sanitation and Safety; Suggestions; Elections; Time and Motion Study; Spoiled Work; Machinery and Tools; Production; Recreation and Entertainment; Attendance and Tardiness; Wages and Rates; Miscellaneous Complaints; Pride and Interest; Eight Hours. These committees are constantly at work on the various subjects within their control. The important point of it all is the fact that through the year and a half's experience there has never been a disagreement between the committees and the management. In many cases the management has been willing to go farther than the committee has suggested.

The outstanding accomplishments have centered around about six of the committees. The Wage and Rates Committee installed a system of classifying men according to their ability and accomplishments, then setting rates to apply to each class. Men are measured according to the specifications laid down for each class, and paid accordingly. Every six months this committee checks our rates with prevailing rates in Cleveland and makes whatever recommendations are necessary. It usually surprises our visitors when we tell them that this committee has, in many cases, refused increases, recommended decreases, and suggested the dismissal of men who were not showing progress.

The Spoiled Work Committee concerns itself chiefly with tracing causes of scrap. They fix the responsibility and suggest measures to prevent recurrence. The work of this committee has had a very decided influence in minimizing our scrap bill.

The Time and Motion Study Committee checks and approves all piece work rates. The result has been beneficial in getting rates set and accepted. Our men know that once a rate has been set it will not be changed so long as the method remains the same, and then only after this committee has rechecked the figures.

The work of the Education and Publication Committee has already been described. All educational activities are under control of this group.

The Eight Hour Committee has succeeded in having our working hours reduced from ten to nine, and, six months later to eight—without reducing production. In fact, now that raw materials are coming in better, production is coming along at a better rate than we have ever had at any time in our history. The work of this committee led them into studies of production and machine methods, resulting in many valuable suggestions; but, of even greater importance, it gave the men first-hand information on the problem of keeping the sales force supplied.

The Pride and Interest Committee is working to give our new men the Multigraph spirit—the living spirit of the craftsman who is doing a job he's proud of. Through the work of this committee new men are given some of the tradition of our business. Twice each week at lunch time in the restaurant we have demonstrations of the various models we make. These demonstrations are arranged and managed by the Pride and Interest Committee and new men are given invitations to attend. There is always a good attendance.

Throughout it all we play up the individual. We appeal to the man to make something of himself. We show him that the Multigraph offers him as broad an opportunity as he can want—and more than that,

# "Obstipui, Comae Steterint"

## The Physical Sensations Accompanying the Emotions of Fear and Horror

By M. Tevis

I WAS amazed; my hair stood on end; my voice stuck in my throat"; such is the stereotyped expression of which the first two clauses stand above, and with which Virgil in numerous passages describes the emotions of the pious Æneas when confronted with some appalling spectacle. We recollect, from our own high school days, the gusto with which this familiar line was translated by the member of the class who might be so fortunate as to find it in his assignment; but we do not recall that it ever occurred to any member of the class to inquire why the emotions of terror had this particular anatomical effect upon Æneas or why they continue to produce the same symptoms in mortals of the present day and generation.

The sensations of fear and horror while entirely mental are indeed accompanied by certain marked and very curious instinctive physical reflexes, which Virgil describes with no exaggeration. Thus anyone suddenly confronted by some hideous or appalling spectacle, such as murder, death through accident, the swift and terrible destruction accomplished by a cyclone, etc., exhibits a blanched skin, a falling jaw, widely distended eyes, and similar changes of aspect. Furthermore, he is apt to feel his heart "stop," *i.e.*, check its pulsation for a moment and then begin beating violently. At the same time a cold sweat may burst from the pores of his skin, he may be seized with a violent tremor and he may feel that curious prickling sensation of the scalp commonly described in the term "my hair stood on end." All these familiar signs of a physical disturbance corresponding to a mental disturbance and occasioned by the latter operate in accordance with certain physiological laws and according to a definite mechanism.

Take the rising of the hair, for instance. The skin is covered everywhere except in the palms of the hands and the soles of the feet with hairs. These hairs are inserted in the skin obliquely, the better to fulfil their function as non-conductors of heat, as a protection from blows (upon the skull), conductors of moisture, etc. However, the hairs are not compelled constantly to retain this prone position since each hair is connected with a minute muscle so attached to its shaft as to exert a pull upon it like that of a rope upon a ship's mast. In those animals which are thickly covered with hair or with feathers this capacity for "bristling" is of great importance, since such a disposition of fur or feathers, which is commonly assumed during sleep, makes the covering of the skin warmer, for the reason that particles of hair—a notably bad conductor of heat, become entangled amid the fur or plumage and thus afford the protection against freezing or chilling which is a greater danger at night, because of the lower temperature and the lessened amount of heat generated by the fact of non-activity element.

But as we have said the hair tends to stand erect not merely through the effect of cold but in response to some mental disturbance. Thus a startled cat at once begins to bristle, which has the practical advantage of making the animal appear more alarming and dangerous to its enemies—a bluff which is often effective. Furthermore, the erected hairs present serried ranks of stiff points which are likely to make it more difficult for the enemy to seize the animal; for instance, an attacking dog would find that these stiff points were not only unpleasant to his sensitive muzzle but also that they compelled him to close his eyes, thus interfering with his onslaught. A magnified section of human skin reveals the reason for the instantaneous physical response to the mental emotion in the fact that the muscles controlling the hairs are connected with the brain centers by specially delicate and numerous nerve branches. This mechanism for the erection of the hair is particularly developed among the apes, which are the supposed relatives of man's forerunners. Writing in *Kosmos* (Stuttgart) for January, 1920, Dr. Fritz Kahn observes that this erection of the hair in animals whether induced by cold, by fright, or by anger is really a somewhat complex affair. Between the muscle whose contraction pulls the obliquely-lying hair to a more erect position, and the shaft of the hair itself, lies the gland of the hair follicle whose office it is to secrete the oil required for maintaining the smoothness and flexibility of the hair. When the fibers of the hair muscle contract this oil-filled gland is pressed tightly against the shaft of the hair so as to force out some of the oil. A very slight contraction of the hair muscle, one hardly sufficient to cause a perceptible motion of the hair itself, is enough to cause a flow of oil. Even such a slight stimulus as washing with cold water, friction with a brush or cloth, etc., is all that is necessary to cause this flow of oil. In the case of a very strong stimulus such as severe cold, violent anger, fright, nausea or disgust, the hair muscle contracts convulsively, bringing the hair to a vertical position, expressed by the term "standing on end." Furthermore, the cramped muscle presses the gland of the hair follicle so forcibly against the surface of the skin as to form little granules upon the latter about the size of millet seeds, thus occasioning the well-known phenomenon of "goose flesh." In the skin of birds these oil glands are comparatively large for the purpose of furnishing oil for the plumage, and for this reason little granules are perceptible even when the plumage is lying flat. Since the nerve impulses in response to which this condition of the skin and hair occurs, travel over the body from the brain as a center, it is natural for a person to speak of his "flesh creeping."

But when the nerves of the hair are excited by any stimulus the other organs of the skin are likewise affected. Thus the thousands of sweat glands in the subcutaneous tissue pour forth their drops of perspiration, thus producing the so-called "cold sweat." At the same time there is a contraction of the minute muscles connected with the delicate veins of the skin, forcing the blood out of all these vessels so that it runs back to the interior of the body, leaving the skin both pale and cold. Thus we have a cold sweat in contrast to the warm sweat due to heat, in which case the skin is warm and red from being filled with blood. Lastly, the combined phenomena here described produce the sensation commonly known in the words "a cold shiver ran down my back."

### Sudden Death Versus Slow Poisoning in the Hudson Vehicular Tunnel

To the Editor of the SCIENTIFIC AMERICAN:

In connection with the proposed construction of the Vehicular Hudson Tunnel for auto traffic, referred to in the SCIENTIFIC AMERICAN of Oct. 9, 1920, and also in the *Literary Digest* of Aug. 14, 1920, Prof. Yandel Henderson, consulting physiologist of the U. S. Bureau of Mines, is quoted to the effect that "If the concentration of CO in the air of the tunnel is kept down to 4:10,000, this concentration will be 'the minimum pollution for a man at rest'"; in other words, if exceptional care is taken that the CO concentration does not exceed 4:10,000, the tunnel will be safe for such traffic to those employed as auto drivers or making use of the tunnel for purposes of passenger traffic.

It has been suggested to me by Dr. Georgine Luden of the Mayo Clinic, Rochester, Minn., who has recently completed some extremely interesting investigations on the clinical after-effects of chronic carbon monoxide poisoning, that in an article on the subject by McGurn to the *Interstate Medical Journal* in 1917, that "a concentration of 1:250,000 inhaled repeatedly for several weeks and months at intervals was found to result in a serious health impairment." Dr. Luden therefore adds that "people using that tunnel, perhaps daily, are therefore going to inhale repeatedly a concentration of CO that is 100 times greater than that which resulted almost fatally in one of McGurn's cases (IV)." She adds further that "Although 4:10,000 CO may not appear to do immediate harm, it is certainly capable of doing harm in the long run and likely to produce a large crop of semi-invalids who may not at first be called neurasthenics but who will end by being ill enough to become invalids for life." McGurn's article is not referred to in Henderson's paper. He may possibly not have been aware of the case reported.

I add to the foregoing a reference to the August number of the *Journal of Pharmacology and Experimental Therapeutics*, in which Henderson and Haggard are very emphatic in their statement that "Within a few hours after profound but non-fatal poisoning with carbon monoxide no trace of the gas is found in the blood. . . . And yet for days, months and even for life structural degenerations and functional chances, usually either nervous or cardiac, may continue." The serious effects of continuous exposure to carbon monoxide have been experimentally ascertained by Dr. Luden, who is of the opinion that there is unquestionably a sensitization to the toxic effects of CO; and that therefore repeated exposure on the part of those who may use the tunnel frequently, assuming the air contamination to be to the extent indicated, will have to be reckoned with.

In a recent dissertation on the Etiological Factors of Carcinoma, submitted to the faculty of the University of Minnesota, Dr. Luden calls attention to the extreme toxicity and ubiquity of carbon monoxide in modern civilized life, the health aspects of which do not seem to have been fully recognized. She concludes that "Absence of noticeable odor, however, does not imply absence of danger. Carbon monoxide is an odorless as well as a colorless gas; its presence would never be detected by our olfactory organ were it not for the addition of the other compounds with which it is usually associated. But even the latter may fail to warn us by their odor. For McGurn was able to show that illuminating gas produced severe clinical symptoms in a dilution of 1:250,000, while Albaugh has recently emphasized the danger of concentrations of 1:2,000. It will be readily conceded that in the first named dilution the presence of the toxic gas was more than likely to escape notice. I might add that since there is a distinct advantage in visualizing the actual value of concentrations by the use of some familiar comparison, a concentration of 1:250,000 may be represented by a small glass of claret (10 cc.) diluted in 625 gallons of water, or in the second instance, mentioned by Albaugh, in five gallons of water. These figures show that the toxicity of carbon monoxide is equaled by its imperceptibility."

I bring the foregoing to your attention as an interesting contribution toward a health problem of present importance. With the technical aspects of this matter I, of course, have only a very slight acquaintance.

Newark, N. J. FREDERICK L. HOFFMAN.

### Prickly Pear Not a Pear at All

To the Editor of the SCIENTIFIC AMERICAN:

My attention has been attracted to the article on "Taking the Pricks Out of Prickly Pear" that appeared in your issue of Sept. 25, 1920, p. 305.

I don't know how accurate you desire to be in articles of such a nature, but I thought it might be wise to call your attention to several misstatements that appear in the article.

Passing the statement that this is a new use (Mr. Burbank commenced to exploit spineless cacti nearly 20 years ago), I'd like to suggest that the so-called "prickly pear" is not a pear at all, that it does not "belong to the big fruit family which (whose) name it bears," and that the part of the plant fed to cattle is not the fruit, but the thickened joints of the stems. Nor is it a "choice ration." As the author states further on in his article, it is an "emergency" feed, ordinarily used only when other more valuable feed is lacking.

The plants referred to (there are a number of species eaten by stock) belong to the cactus family in the genus *Opuntia*. Certain species of this genus have flattened, fleshy stem joints that are circular to ellipsoid in outline and from a few inches to a foot in length. These species go by the common name of "prickly pears" and this name is also applied to the globular to pear-shaped fruits, some varieties of which are to be found at the better class fruit stands in the larger cities of this country.

These plants are cultivated extensively in Mexico where the joints and fruits are used in a number of ways. They call the plant *no-päl'* and the fruit *tu' nä.*

Washington, D. C. E. O. WOOTON.

# Fuel or Fertilizer?

## America's Little-Known Peat Bogs and the Uses to Which They Are Being Put

By Harry A. Mount

THE word "peat" conjures to the average mind the picture of an Irish moor, with a few old men and women at the back-breaking task of spading up cubes of turf and piling them in the sun to dry for fuel. A view of one of the American peat bogs which is being worked would be a surprising sight.

**Hauling the peat from the bog to the fertilizer factory by means of a diminutive locomotive and dummy cars**

One glimpses, not a great swamp waste, but an area as flat as a table and nearly as smooth. Part of it is green with a magnificent crop of celery or onions; over another part tractors drag plows and harrows, and great machines strange to the eye ply back and forth. At one corner of the bog stands a good-sized plant where the peat is turned into products of commercial value; and near it are mammoth storage piles of the black loam.

Because we in America have had heretofore an abundance of virgin land and plenty of coal we have generally overlooked the value of our peat bogs. Indeed many will no doubt be surprised to hear we have any such thing in this country. Our Bureau of Mines estimates that there are in the United States about 12,000 square miles of workable peat bogs, besides a great number of beds advantageously adapted to agricultural purposes.

Aside from its value as fuel and its use in agriculture, peat has a score or more of uses, and its field is being constantly widened. A long list of chemicals are extracted from it. These include ammonia, methyl alcohol, acetone, acetic acid, pyridines, mono-phenols, a gasoline-like spirit, some neutral oils, paraffin wax, tar, and dyes.

The medicinal qualities of peat baths have made them popular in some sections of the world. During the war hundreds of tons of peat moss were used as an absorbent in dressing wounds. A process has been patented in England for making paper from the vegetable fiber found in peat bogs. By mixing molasses with properly prepared peat a food for cattle is made which is used widely in England and Germany. There are other minor uses.

A few plants are operating in this country and Canada for the production of fuel from peat and for the by-products. As a fuel, peat has about sixty per cent the heating value of coal, ton for ton. But it can be produced very cheaply, and since European practise has already shown it can be used successfully in the industries and even in firing locomotive boilers, there is little doubt that it is a coming fuel. More will be said of this phase of the subject in another article.

By far the largest use for peat in this country thus far is in agriculture and in the production of fertilizers. The industry is a new one. In 1914 the total value of the peat consumed in this country was $367,000, of which about two-thirds was used for fertilizers. In 1918 the peat used was valued at $750,000 and although official figures are not available for 1919, the value is believed to run well over a million dollars. Of this perhaps even a larger percentage than in 1914 was used for fertilizers.

To understand the production of fertilizer from peat, it is necessary to know something of the nature of these natural deposits.

Peat deposits are built up by water plants on the beds of lakes—plants which die down annually through many years, until the deposits reach the surface and the lake is turned into a swamp. It is in this state that the peat is usually found.

The plants, as they die, are preserved by the water and a process of very slow decay takes place. If the bog is a young one, the muck which composes it will be of a fibrous nature, but if the bog is a very ancient one the fibers may have disappeared entirely and the muck will be a fine-grained loam when dried.

In its natural state peat may consist largely of water; and even after the bed has been drained the peat has a moisture content of about 90 per cent. The peat retains the water just as a sponge does and before the product is of commercial value the water must be reduced either by sun drying, pressing, or with evaporating machinery.

**Putting peat on a commercial basis. The driers in the peat plant**

The value of peat as a fertilizer lies principally in the fact that it is very rich in the essential plant food, nitrogen, but lime, potash and phosphoric acid added to produce a "balanced ration." But of scarcely less importance is the fact that it provides an ideal habitat for the billions of tiny bacteria which infest all soil and whose activities convert these food-chemicals into a form which the plant can assimilate. In fact, the presence of the nitrogen in the peat can be attributed to these little animals, so tiny that thousands of them can be collected on the head of a pin.

Under the microscope these bacteria are seen to be animals of the lowest form, which reproduce themselves by splitting into two parts. Under favorable conditions two bacteria grow from every one every forty minutes. Those who wish to carry out the mathematical progression will find that a single bacteria will have increased to about 165,000,000,000,000 in twenty-four hours. Of course many, many billions of them die in that time, or they would soon overrun the planet and crowd off every other form of life.

Have you ever pulled up a clover root and noticed the little balls, like tiny potatoes, clinging to it? Within these balls are millions of the particular bacteria which thrive upon the roots of clover. And each of these little balls represents the additions of so much nitrogen to the soil, for these bacteria have the power of drawing nitrogen from the air. It was known, long ago, that corn or potatoes grew better in a field which had had clover in it the year before and it has become a common practise for farmers to plant clover and plow it under as a fertilizer.

Another variety of bacterium clings in a similar way to the roots of beans, and another to peas. The plants of this family all have the peculiarity of attracting beneficial bacteria under favorable soil conditions. They are called legumes, and the little balls which gather on their roots are called nodules.

It was once the practise, when a field of clover failed to produce the nodules, to carry soil from another field of clover; and in this way the new field was inoculated with the bacteria. The farmer did not know why he did it, but with the forward march of science these bacteria were isolated, their habits studied, and they were artificially bred in gelatins. These gelatins could be purchased, mixed with water and the bacteria sprayed over the land, or mixed with the seeds which are to be grown there. But it was necessary to buy a different gelatin for each separate crop. A search for a strain of bacillus that would be universally useful proved fruitless. And then the happy discovery was made that peat is an ideal home for all varieties of these bacilli and the problem was attacked from a different angle. All of the different breeds were introduced into the peat; now this inoculant may be used for any of the

## A Tractor That Turns in the Space It Stands On

By Ralph Howard

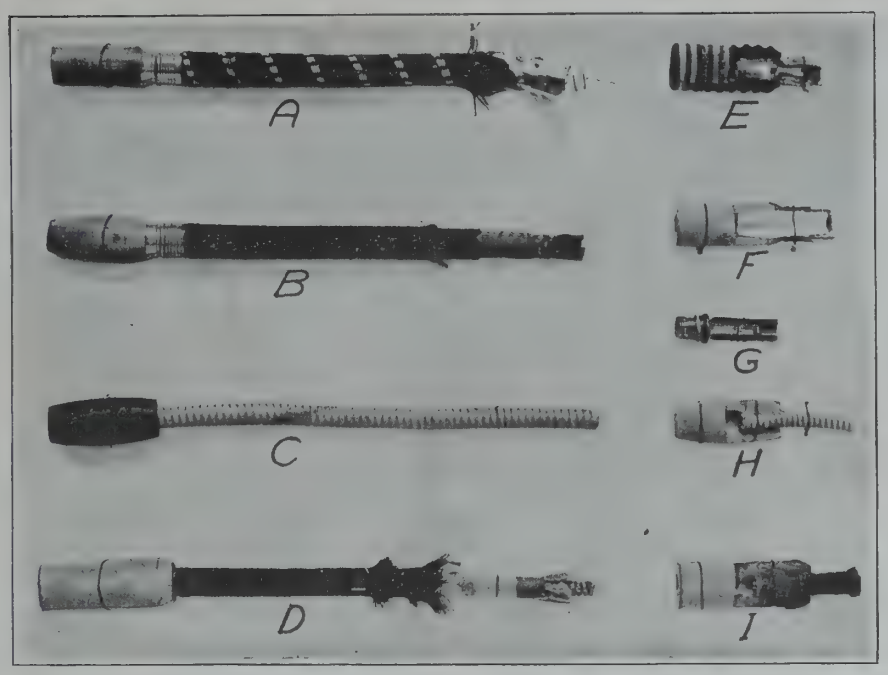
WONDERFUL as has been the progress in tractor development in the past, tractor engineers and manufacturers see a further step forward in a tractor constructed on new basic principles now being exhibited in California. Primarily, this tractor is a round-wheel type, having four wheels of equal size with the power distributed equally to all four. The wheels are arranged in pairs on the tractor and held against lateral turning movement relative to the tractor, the wheels on either side of the tractor being connected in driving relation with each other, but only one pair being connected with the power unit of the tractor. The wheels on either side of the tractor are turnably mounted on their axles independently of those on the other side and the driving connection has been arranged to be susceptible of being interrupted relative to either or both pairs of the wheels. On either side the wheels are as readily locked against rotation as they are released from their driving connection. By this means the tractor may be steered in arcs of various radii, or it may be steered at right angles to itself when short turns are made.

With the driving means so controllable as to permit the machine to be turned in arcs, the radii of which may be less than the length of the machine and from that up to any length desired by the operator, according to conditions under which the machine may be working, it became necessary to mount on the periphery of the wheels leaders of such shape and design as to permit the machine to turn without causing the leaders or guides to plow the ground. None of the wheels can be used as steering wheel independently of the tractor as a whole, but when a turning movement is to be imparted to the tractor the entire machine is turned in a rigid movement with the power so applied as not to cause any undue lateral strain on any part of the tractor. The whole operation is carried out with a pivot-like movement, produced primarily by the peculiar construction and arrangement of the leaders or guides on the wheels.

These are so constructed and mounted on the wheels that in a turning movement the leaders on the inside wheels, or non-rotating wheels, act as guides to direct the pivotal movement, but a directly opposite effect is had on the outside, or rotating wheels, to which the power is wholly or in part applied. The diameter of the circle of movement of the inside wheels may be increased or decreased by clutch control, through a relatively small movement of the steering wheel, but the general operation and function of the parts will still be present in the relation described. The entire turning movement is carried out with minimum lateral strain on the wheels or machine as a whole. A slight movement with a minimum of power is obtained by both ends of the guides being beveled so that there is a lifting effect tending to raise the wheels out of the ground instead of causing the wheels to plow the ground, as they might do were they not so beveled. The angle at which the guide may be set with respect to the axis of the wheel to obtain the maximum turning ability has been determined by practical trials. The turning movement can only be successfully accomplished when the guides are so set with respect to the axis of the wheel. The same successful turning can be done in forward or backward movement. Maximum gripping effect is necessarily of prime importance, and is secured without tearing the ground by giving depth to the leaders.

Equally important in facilitating the turning movement is the application of the power to the drive wheels. Through a specially designed transmission in which the maximum amount of power is delivered, due to the simplicity of construction, the driving power is readily applied or removed from the two wheels on either side. By the application of this power to the front wheels an equalization of power is obtained on all four wheels, which overcomes any tendency for the front end to rear up no matter how great a load the tractor may be pulling, nor how suddenly the power may be applied to the wheels. The power is evenly distributed on all of the wheels.

The operation of the tractor is simple. The operator is comfortably seated with the clutch pedal and gear shift lever at hand, and he has easy control of the movement of the tractor by a neat steering wheel. This wheel, by slight movement, operates a cam control, through which the power is applied or released from either side of the tractor. Further movement of this wheel locks the wheels on either side of the tractor. By this steering mechanism two wheels on one side of the tractor are simultaneously released and a brake applied to them with effective results.



**Four types of flexible gas tubing and five end connections which were tested by the Bureau of Standards, with the results set forth in the text**

## Gas-Tubing Tests

By S. R. Winters

THE door is unfastened, the occupants of the room are found cold in death, the reason is unmistakable—briefly summarized, another tragedy is traceable to escaping gas. Not improbable, the leakage of the death-dealing fumes had its source in faulty gas tubings. Recognizing the hazards to life and property incident to unsatisfactory gas conveyances and connections, the Gas Engineering Section of the United States Bureau of Standards has conducted a series of experiments with relation to nine types of gas tubings, the results indicating their relative safety.

The manufacturer who wrote the Bureau of Standards, "The demand is very largely for the cheapest tubing that can be turned out that will stay tight long enough for it to be sold," probably reflects the levity with which flexible tubing and tubing ends are installed. The design which is constructed of paper, covered with glue, on a wire spiral, being covered with a cotton braiding of inviting appearance is pronounced dangerous by the Gas Engineering Section of the Government. The photograph herewith displays the nine types, the text describing each being supplied by the Bureau of Standards as follows:

(A) A dangerous type of tubing constructed of paper, covered with glue, on a wire spiral, the whole covered with a cotton braiding giving it a good outside appearance. The glue soon hardens and cracks upon bending the tubing.

(B) This tubing, constructed like a garden hose of cotton fabric impregnated with rubber, is flexible, gas-tight, but dangerous if subjected to high temperatures.

(C) The common type of metallic tubing, which depends for its tightness upon a rubber thread packing within the metal spiral. This rubber thread deteriorates with age, especially if overheated, causing small leaks in the tubing which might allow dangerous quantities of gas to escape, though not presenting much fire hazard.

(D) A very good grade of flexible tubing constructed of a gas-tight metal core covered with successive layers of paper, fabric, glue-glycerine compound, paper, and two braided coverings. It has the advantages of a metallic tubing of type (C) with some additional durability due to the superimposed layers.

(E) A very satisfactory type of tubing end piece if constructed of good quality materials. It consists of a threaded metal tail-piece, one end of which is screwed into the tubing and the other end is screwed into the rubber end piece, making the connection about as strong as the tubing itself.

(F) A common, but not always satisfactory, connection, consisting of a wood tail-piece glued into the tubing and rubber end. The gas passage is unduly restricted. The strength and durability depend upon the quality of glue used and the care with which the end is attached.

**Two views of the new tractor, showing the sharpness with which it will turn, and the manner in which it attacks an obstacle**

# The Traffic Problem in New York City

## Subway Extensions to Take Care of an Ultimate Annual Travel of Nine Billion Passengers

THE construction of adequate rapid transit facilities for the city of New York is rendered particularly difficult by certain special conditions which control the problem.

Foremost among these are: first, the unfavorable topographical condition that the heart of the city, to and from which traffic flows in the rush hours, is situated on the lower end of an island which is separated from the surrounding territory on the south by the broad waters of New York Bay, and on either flank by the wide and deep North and East Rivers; second, the vast population now amounting to nearly 6 million which is to be served; and third, the fact that the growth of travel takes place at a steadily increasing ratio.

Not only is the business center of Greater New York so far as regards transportation, pocketed at the southern end of Manhattan Island, but the great development in the number and height of tall office buildings has brought a corresponding increase in the density of the working population during business hours, with a corresponding added congestion of the transit lines.

### Commencement of Rapid Transit

Rapid transit in New York City commenced about fifty-two years ago, or in 1868, and consisted in the first place of surface horse-drawn cars. These were supplemented about ten years later by the elevated railroads, and in 1904 the first of the subways was opened. It was not until the beginning of the present century that the city fathers began to get some glimmering of the stupendous problem which confronted them in the attempt to keep pace with the growth of population and business concentration in lower Manhattan, and the growing tendency for the business population to make their homes in the suburbs. At that time the streets were occupied by surface and elevated tracks and because of their noise and unsightliness it was realized that the public would never agree to the construction of additional elevated lines on Manhattan. Consequently, the only available field for enlargement was underground. Thus the idea of the construction of subways had its birth and an active campaign was carried on to enlist public sympathy and support.

The first subway system was opened in 1904, and it not only verified all the predictions of its sponsors, but was so successful that it carried a total number of passengers far in excess of the most sanguine estimates. Forewarned by the growing popularity of the subway, the rapid transit commissioners immediately formulated plans for its extension; but nothing material was accomplished until 1913, or nine years after the first subway was put in operation, and traffic had caught up.

### The Dual Subway System

Then the so-called dual subway system was consummated and contracts were made between the city and the existing Interborough Rapid Transit Company and the New York Municipal Railway Corporation. The dual system, which practically doubled the trackage and trebled the capacity of the then existing rapid transit facilities, is very nearly completed, but its construction was greatly delayed and its cost practically doubled during the war. The whole system will carry about 2,400,000,000 passengers during the year 1920, and when the last extensions have been completed and everything is in full swing, it is estimated that it will accommodate about 3 billion passengers. Already, in spite of the increased facilities, the subways are heavily congested, and every citizen who uses them will agree that the city should push the system to completion with all possible dispatch, and in the meanwhile lay its plans for further extensions to meet the demands of the future.

An exhaustive study of this subject is found in a report by Daniel L. Turner, Chief Engineer, which has recently been submitted to John H. Delaney, the Rapid Transit Commissioner for this city. Mr. Turner's report is divided into two sections, one dealing with the requirements of the next twenty-five years, and the other with the probable needed extensions of the next seventy-five years, or, say, up to the close of the present century. The larger scheme is presented by the map and drawings found on the first page of this issue, but it should be carefully noted that it is not the intention, nor is it recommended, that the whole of this scheme should be put into execution at once, but only such parts of it as will be sufficient to meet the needs of the city up to the year 1945.

The estimates for 1945 and 1995 are based upon a study of the rate of growth of traffic during the present century, and particularly during the decade 1910 to 1920, and also upon the rate of growth of the population of greater New York. The figures represent the total travel of all systems of transportation, street-surface, elevated and subway. They show that in 1910 the total number of passengers on all systems was 1,527,000,000. This has increased to 2,400,000,000 in the year 1920, and if the growth in population and travel continues at the same rate, the city will have to provide for an annual travel in 1945 of 5 billion passengers, and in 1995 of over 9 billions.

### Early Construction to Meet the Necessities of the Next 25 Years

The extensions which are recommended to be commenced immediately, and the work to be done in finishing up of the present dual system are as follows: Extension of Corona Branch of the Steinway tunnel line to Main Street, Flushing; also, on Manhattan, the extension of the Steinway tunnel line from Seventh Avenue and 41st Street west to connect with the proposed Amsterdam Avenue—Eighth Avenue Trunk line. A two-track extension of the present Broadway-Fourth Avenue line from 59th Street up Central Park West to the Harlem River; and extension of the Broadway-Fourth Avenue line from City Hall Park by way of Ann Street to East River to a connection with the Fulton Street elevated line near Ashland Place, Brooklyn. An extension of the Fourth Avenue subway, Brooklyn, by way of a two-track tunnel under the Narrows to the Borough of Richmond. An extension of the Nostrand Avenue subway to Coney Island. An extension of the Astoria Branch of the Steinway tunnel south through Queens and Brooklyn to a connection with the Brighton Beach line, thereby providing a Brooklyn crosstown line. A two-track extension of the Seventh Avenue-Broadway line from a point at Greenwich and Liberty Streets by Maiden Lane and the East River to Brooklyn, and thence by Hicks Street to a connection with the Culver line.

### New Trunk Lines

In the Borough of Manhattan two additional trunk lines are to be built, one extending below Eighth Avenue and Amsterdam Avenue from 23d Street to 155th Street. This will be the most important trunk line of the whole subway system, for it will be a double-decked structure, four tracks upon each level. The immediate construction will include only four tracks of these eight.

There will be a collecting and distributing branch from 155th Street to upper Manhattan and the Bronx, by way of Fort Washington Avenue to Spuyten Duyvil, and thence by Netherland Avenue through the Riverdale section. From its southern extremity a branch will extend through 23d Street to the East River, and another branch will extend south down Hudson and Washington Streets to the Battery or South Ferry.

The immediate 25-year program calls also for a new East Side Manhattan trunk line, consisting of four tracks of what will ultimately be a six-track trunk line under Madison Avenue, reaching from 23d Street to the Harlem River and having a two-track collecting and distributing branch from 23d Street down Fifth Avenue and lower Manhattan to some point near Park Place.

### Crosstown Moving Platform

The crosstown traffic and cross-over passengers from the East and West Side northerly to the West and East Side southerly portions of the various trunk lines are to be accommodated by moving platforms which, because of their great capacity, are well adapted to take care of this class of traffic where capacity is of more importance than speed. For the 25-year program there will be three moving platforms located respectively at 14th Street, 42nd Street, 57th Street, to be followed after the 25-year program is completed by others through 23d and 34th Streets.

Chief Engineer Turner's report states that it is impracticable to estimate the construction cost of this 25-year program because of the long period over which the work would extend. At pre-war prices it is estimated that the cost would be in the neighborhood of 175 million dollars, but at present prices the cost would amount to 350 million dollars. In all probability the cost will be intermediate between these two figures. In conclusion, we cannot do better than quote the final paragraph of this report, for upon the full recognition of the principles therein laid down, depends undoubtedly the success of our future transit operations.

"The new transit lines should precede the population. The new transit plan should be the basis of the city plan. Upon these two cardinal principles the future of the city depends. The foresight exercised in developing its transit facilities and in conforming its future expansion thereto will largely determine the prosperity of New York City in the years to come."

*Do You Know That—*

The transportation system of New York City—street cars, subways and elevated lines—carried 1,527,000,000 passengers in 1910.

These lines carried 2,400,000,000 passengers in 1920.

It is estimated that in 1995 they will be called upon to carry 9,000,000,000 passengers.

To accommodate the existing traffic there are, in addition to the elevated and surface lines which hardly admit of extension, 616 miles of single-track subway and 34 tunnels beneath the waters about the city.

To accommodate the traffic of 75 years hence it will be necessary to build 830 miles of new single-track subway and 42 new sub-aqueous tunnels.

At present prices, so much of this program as is likely to be called for by the traffic needs of the next twenty-five years will cost some $350,000,000.

Such is New York's rapid transit problem.

## Radio-active Pottery

A NEW method of applying the well-known healing properties of radium is reported in a German magazine. Many natural waters have been found to be radio-active and their presence in the springs of certain resorts has undoubtedly occasioned or added to the fame of these, but it has been discovered that any kind of water can be made radio-active by the action of radium, consequently some one has had the ingenious idea of simplifying this process by making jugs and other vessels of radio-active clay. It has been found that certain clays employed in the manufacture of pottery readily lend themselves to a mixture with radio-active substances without injury to their ceramic qualities, especially the property of being readily molded and fired. The most important radio-active substances employed are the uranium pitchblend which is found in considerable quantities in the Joachimstal in Bohemia, and the mineral called Fergussonite, as also the residues remaining from the working of uranium ores.

These substances are mixed with the clay which is then molded into the desired shape and fired. Certain precautions must be observed, however, during the firing—in especial the clay must be prevented from becoming too much vitrified and contracting too greatly. It must, on the contrary, preserve as large as possible an external surface and thus remain porous in the interior. This is accomplished by a suitable modification of the firing process. The vessels thus prepared are first sprayed with fused aluminum and then receive a thicker layer of metal (copper or brass). When water is poured into a jug thus prepared it becomes highly radio-active in the course of a few days. Instead of jugs clay tubes can be manufactured in the same manner and simply slipped into ordinary drinking vessels. The radio-active water obtained in this manner is used not only as a curative agent but it is suggested that it be employed for the watering of plants, since it has been discovered that radium is favorable to the growth of vegetation.

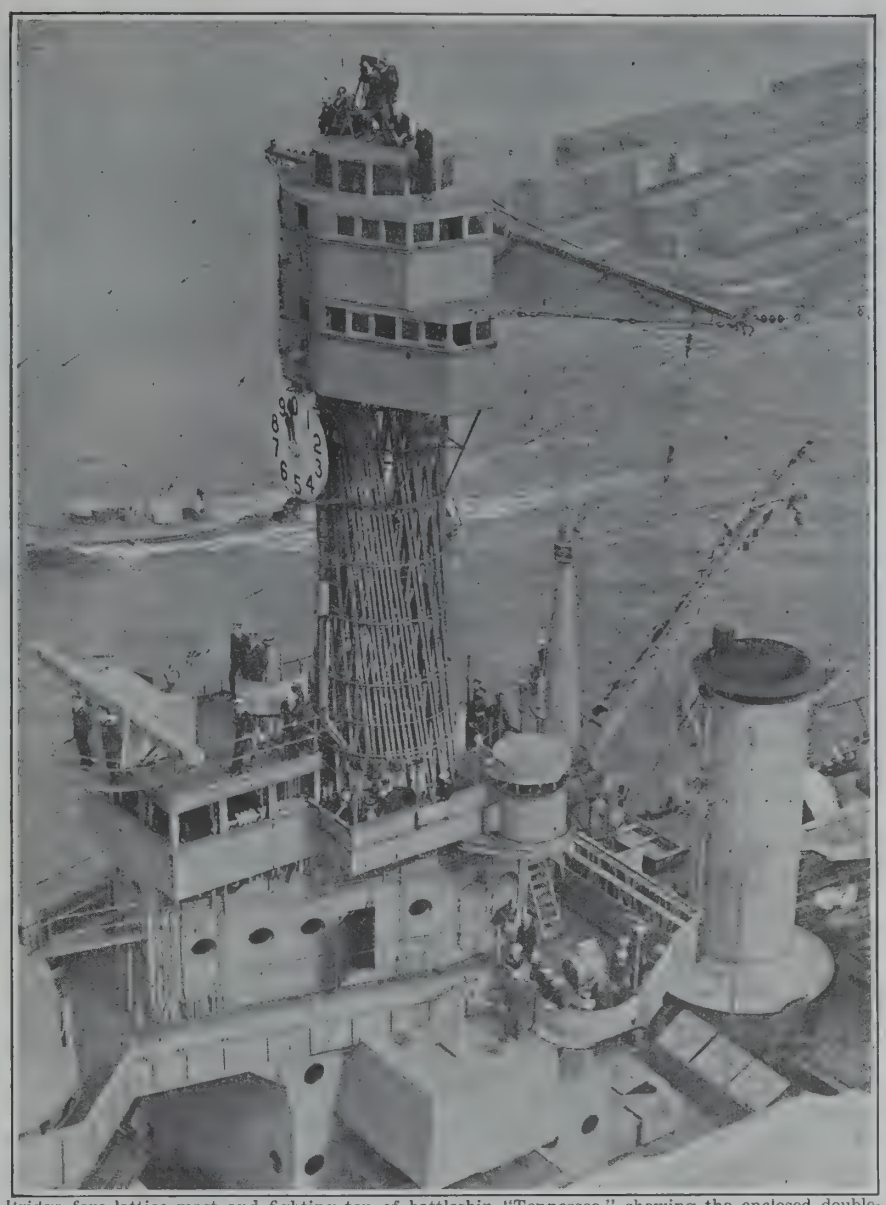
## "Tennessee"—Our Latest Battleship

### A Ship Which Embodies Many of the Tactical Lessons of the War

THE battleship "Tennessee" (sister to the "California") which was laid down at the New York Navy Yard in May, 1917, recently left for a "shaking down" cruise to Guantanamo, Cuba, at the conclusion of which she will be given her speed trials for acceptance by the Navy Department. Her principal dimensions are: length between perpendiculars, 600 feet; beam, 97 feet, 3½ inches; mean draft, 30 feet 3 inches; normal displacement, 32,300 tons; and full load displacement with 31 feet of draft, 33,190 tons. Her motive power consists of a Westinghouse turbo-electric drive, with two main generators and four propelling motors. In the boiler room are Babcock and Wilcox oil-fired boilers, and her estimated shaft horse-power is 38,500. The main battery consists of twelve 14-inch, 50-caliber guns which are emplaced in four 3-gun turrets, all of which are mounted on the center line of the ship and are available on either broadside. The secondary battery, which is mounted in casemates on the spar deck, and upon the boat deck, consists of fourteen 5-inch, 51-caliber guns. For anti-aircraft defense there are four 3-inch guns. The "Tennessee" mounts two torpedo tubes, one on each beam, for firing the 21-inch torpedo. The complement of the ship is made up of 130 officers of all ranks, and 1,281 men. An unusually large part of the displacement of the ship is given over to armor protection, the belt having a maximum thickness of 14 inches. The funnel bases are heavily armored. The port plates of the turrets are 18 inches in thickness.

A great deal of thought has been given to protecting the ship by limiting the inflow of water below water line, caused by shell fire or torpedo. Between the outer shell of the ship and the engine and boiler rooms, magazines, and other vital elements, there are several longitudinal walls of steel which are intersected by numerous transverse bulkheads. This provides the ship with a wide cellular belt, whose effect will be greatly to limit the flooding which results from the successful blow of a torpedo. Also, the vitals of the ship are protected from shell fire by several stout steel decks which, it is hoped, will serve as shell bursters and by breaking up the shells prevent any penetration below the protective deck.

During the service of our Sixth Battle Squadron with the Grand Fleet in the North Sea, there was a very free exchange of ideas between our own and the British navies, as there was also between the various departments of the two navies, and when our squadron returned to this port they presented to American eyes several new features which they had brought with them from the area of naval operations. Several of these features have been embodied in the "Tennessee," with many improvements worked out in our own department. Among our own developments is the large enclosed structure at the mastheads which takes the place of the old, open, fire-control platforms as they were known in our navy in pre-war days. These enclosed "tops" were necessitated by the improvements in director firing, in which the aiming of the guns is controlled by officers stationed in lofty positions and preferably at the masthead.



Bridge fore lattice mast and fighting top of battleship "Tennessee," showing the enclosed double-deck structure in which the directorscope and the instruments for finding and keeping the range of the enemy and his bearing are housed, together with the fire-control personnel. Note the close massing of the latticed tubing, to ensure rigidity.

**The new-type fighting top of the "Tennessee"**

In no direction has there been such progress as in this matter of gunnery. Both in the British and in our own navies some really wonderful instruments have been devised for finding the range and bearing of the enemy and keeping on the range in spite of the deviation of one's own or the enemy ship. Among these may be mentioned range-finding instruments, target bearing instruments, and those for range keeping; and, of course, there is the form of telescope known as the directorscope. It has become necessary to give ample protection both to these instruments and the officers and men who operate them. This accounts for the remarkable double-deck structure which is such a conspicuous feature at the head of each of the lattice masts of the "Tennessee." It will be noticed, by the way, that these masts are very much more massive in construction than those of our earlier ships. This change is due to the necessity of damping out as quickly as possible the intense vibrations which are set up in the structure of a battleship and particularly at the mastheads, when a salvo from its big guns is fired. Also, it is desirable to reduce to a minimum a certain amount of springing of the masts, due to inertia when the ship is rolling or plunging heavily. The British use a combination of three very stout steel masts arranged in tripod form. Doubtless, this gives a stiffer platform; but in the opinion of our Navy Department, the tripod mast could be more easily shot away or seriously disabled than our lattice masts, which are made up of a very large number of spirally grouped steel tubes.

Another development of the war is the use of director firing, not merely for the main battery, but also for the 5-inch torpedo battery. These, of course, have to be separate installations and hence we have the two separate director rooms, one above the other.

Another conspicuous feature which will be new to American eyes is the large clock face at the front of the foremast. This is a British device which gave satisfaction. It is used when a fleet is steaming in column to indicate to the ship ahead and the ship behind (there is another clock on the rear of the main mast) the speed at which the ship is traveling—a necessary precaution in keeping proper distance and station. At the foot of the foremast and some distance ahead of it is a large covered range-finder, and below this is the navigating bridge. Below the bridge where we see the circular port holes is the chart house which is surrounded by the signal bridge. A group of signal men will be noticed in the right-hand corner of this bridge, with the racks for the signal flags behind them, and the signal halyards leading up to the signal yard at the top of the mast. Forward on this bridge will be noticed the top of the conning tower.

# First Aid for Inventors

## The Franklin Institute and the Committee Through Which It Assists Meritorious Patents

### By William A. McGarry

UNKNOWN inventors storming the citadel of fame with brains and mechanical or scientific ingenuity too often discover that these resources are of relatively little value in finding a market for their achievements. It has been said that the hardest part of the inventor's work begins after he has obtained his patent, when he starts the weary grind from office to office seeking financial backing to commercialize the product.

Yet for nearly a century one of the world's most famous scientific institutions has maintained a corps of experts "to examine and make report upon all new and useful machines, inventions and discoveries submitted to them." The individual services of the members of this corps command anywhere from ten to a hundred thousand dollars a year, and the wealthiest corporation in the country would go bankrupt if it tried to hire all of them. But inventors may have their advice for the price of postage stamps.

These men are the members of what is now known as the Committee on Science and the Arts of the Franklin Institute, founded in 1824 at Philadelphia as a memorial to Benjamin Franklin and for the promotion of the mechanic arts. Free scientific examination of appliances and processes was one of the first functions of the institute. In the beginning the work was done by a "Board of Examiners." Later it was turned over to a "Committee on Inventions," and in 1834 the present committee was established. Until 1886 membership on the committee was open to any member of the institute, but in that year it was decided to limit the body to forty-five members "who shall pledge themselves by their acceptance of membership to perform such duties as may devolve upon them, and to sustain by their labors the scientific character of the institute." Still later the number was increased to sixty members.

The work of this organization in behalf of inventors is not intended to provide easy access to unlimited capital, but that, in effect, is what it does when an invention is of sufficient importance to warrant even a favorable mention. When the appliance or discovery means as much to the mechanic arts and to society at large as Moissan's electric furnace, Owens' bottle-blowing machine, Pupin's discovery of the art of reducing attenuation of electrical waves and apparatus or Turner's air brake, to mention a few random items out of hundreds, the committee is empowered to award the Elliott Cresson gold medal and other similar honors.

In general, however, it may be said that these higher awards are for contributions to the world's store of knowledge that the unknown inventor rarely makes with his first achievement. To obtain the committee's certificate of merit it is not necessary that the inventor be a distinguished man of science. And from the financial point of view this certificate is just as valuable to him as the Franklin Medal, which is awarded to scientists of international repute like Marconi, one of the winners last year.

Publication of the award is made in the journal of the institute, with the result that within a few months the invention is brought to the attention of every large corporation in the world maintaining a research laboratory, every organization of scientists and all the best technical schools and colleges. The records of the institute show that by far the greater proportion of the discoveries recognized by its Committee on Science and the Arts or its predecessors in ninety-six years have come into wide commercial usage within a relatively short time. With the approval of the experts on this committee for his achievement it is no exaggeration to say that the inventor may make his own selection of capital offers, instead of being compelled to spend his time seeking to enlist financial aid.

Only one thing is necessary for the inventor who seeks this approval—he must have something of real value. It is not essential that it be in use. For obvious reasons, the institute will not consider an invention until a patent has been granted, nor will it act where a patent is in litigation except where this action will not infringe on the rights of either party. The regula-

**Three views of the miniature circus, showing the owner and the menagerie, interior of big top, and a bird's-eye view of the entire plant**

## The Circus in Miniature

OF miniature sailing vessels, steamers, electric and steam locomotives, houses, gardens, skyscrapers and so on, there seems no end. But when it comes to the circus in miniature, it appears as though we have hit upon something a little out of the regular run of model work.

Here is a young model maker who has constructed a remarkable miniature circus. The first of the accompanying views shows the menagerie tent and the owner of the show, together with some of the cages. The present plant has 60 wagons all told, including baggage, parade, official, cages, and so on. The owner plans to increase his circus to 85 wagons for the 1921 season.

The second view shows the interior of the big top. The center poles are 16 inches high. This tent contains a hippodrome track, three rings, two stages, and aerial apparatus. There are general admission seats, reserved seats, and a grandstand. Three hundred stakes are required to hold this tent.

The third view is a bird's-eye view of the entire circus. In the immediate foreground is the side show. Beyond it is the marquee, or entrance, which leads into the menagerie tent. At the right is the big top, which measures 6 by 12 feet. Other tents are the horse or stable tent, dressing tent, two smaller private dressing tents for star performers, blacksmith tent, cook-house and dining room.

## The Voice with the Megaphone Wins

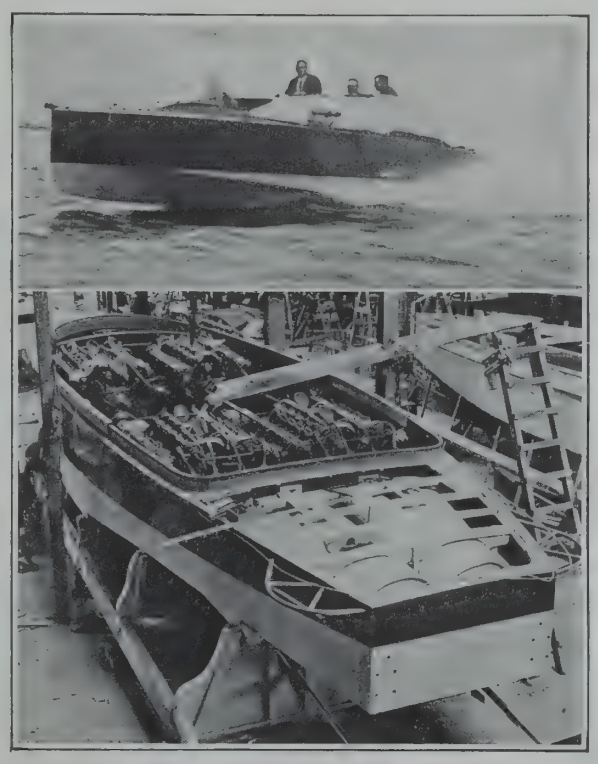
REMARKABLE progress has been made ever since the Liberty and Victory Loan drives in the art of addressing large gatherings. Not so many years ago a public speaker was limited to a crowd of but a few thousand persons when speaking in the open air. Today, thanks to the various amplifying systems and loud-speaking telephones now being employed, a speaker can address 50,000 persons without difficulty.

A remarkable installation of loud-speaking telephones and megaphones is shown in the accompanying illustration. Here is the speaker's stand recently built in Boston for political purposes. The speaker's voice is gathered by an arrangement of microphones in front of him, amplified by vacuum tube circuits, and propagated by means of the loud-speaking telephones and megaphones in all directions. This system of centralized distribution is generally better than the method making use of numerous scattered loud-speaking units.

**A speakers' stand suitable for addressing 50,000 persons in the open**

## The Highest-Powered Motor Boat Afloat

IT will be remembered that one of the contestants built for the Harmsworth Cup races was "Maple Leaf V," owned by Sir E. M. Edgar. In the races she was piloted by H. G. Hawker, who, it will be remembered, made an unsuccessful attempt to fly from Newfoundland to Ireland. We publish these pictures of the boat because of the enormous power plant which was



**Two views of the "Maple Leaf V," which has a combined horse-power of 1,800**

crowded into her; for although she is only 39 feet in length, it was found possible to crowd into her four 450-horse-power Sunbeam engines, together with the tanks of large capacity which were necessary to carry the fuel. One of our pictures shows the four engines placed in pairs side by side. So big was the power plant that it was difficult to find room for the crew's quarters.

The "Maple Leaf," in spite of the fact that she carried twice the horse-power, was easily beaten by "Miss America," which on a length of 26 feet carried only two Liberty engines of a combined horse-power of 800, or less than half the horse-power of "Maple Leaf V." The best speed made by "Maple Leaf" was during her trials, when she reached 62.4 miles per hour; "Miss America" was credited with having made 71.4 miles per hour and was much easier to handle when racing than her rival.

## A New Engine

A LA RHONE engine, made of Sheffield steel, has been presented to the Sheffield University. W. H. Allen, the donor, stated that the engine, although of French origin, is to be made in England by request of the British Government, and the output has been increased from 3 to 50 a week. Altogether 3,000 La Rhone engines have been turned out by the British manufacturers.

The engine is a 9-cylinder rotary type, weighing less than 3 pounds per horse-power. The purpose of the engineers is to produce an engine developing 2.5 horse-power per pound of weight. The La Rhone engine is said to be of startling design. At 1,300 revolutions per minute it develops 100 horse-power, though it can stand on a small drawing table. Dr. Ripper, of the engineering department of Sheffield University, predicts that the next step will be the development of a gas turbine running at a higher revolutionary speed with greatly reduced weight per horse-power.

## Front-Wheel Drive

A MOTOR car improvement, which makes possible the driving of the car from the front instead of the rear wheels, has been invented by G. I. Hoskins, of Sydney, Australia. J. I. Brittain, American consul at Sydney, gives an account of the invention in a report to the State Department.

Mr. Hoskins claims that his invention is a positive success and prevents skidding. A test over 16,000 miles of rough road has been made, it is claimed, with no signs of wear. A number of patents have been taken out.

The front wheels are pivoted in the center, which enables the steering of the car with much greater ease than in the rear-wheel-driven machine. The device is now attached to an old worn British car which, prior to the attachment of the device, weighed 32 hundredweight, with a speed of 38 miles an hour, traveling 15 miles on one gallon of gasoline. After alteration and application of the front drive device, the car weighs 35 hundredweight, has a speed of 45 miles an hour and will go 17½ miles on a single gallon of gasoline.

## An Interesting Pole Construction That Turns Transmission Line

AN interesting pole rack has been constructed for turning a transmission line along the St. Joseph River in Michigan. Spanning the river at this point the transmission line is supported on one side by strain insulators attached to the hydro-electric power house and by a rectangular tower on the other. The lines are turned parallel to the river a short distance beyond the steel tower by means of a wooden tower of four poles formed in a square. A strain tower was erected beyond the corner tower so that the main line strains would not be carried by the wooden structure. The corner tower is, in reality, only a support of splices between the lines running at right angles from this point. Each arm supporting a conductor is guyed back to a short stub pole set and anchored beyond the corner tower, and not shown in this view.

**This wooden structure serves to support the power cables at the point where they turn**

# Inventions New and Interesting

**Serving as a side car, the canoe may be transported anywhere in quick time**

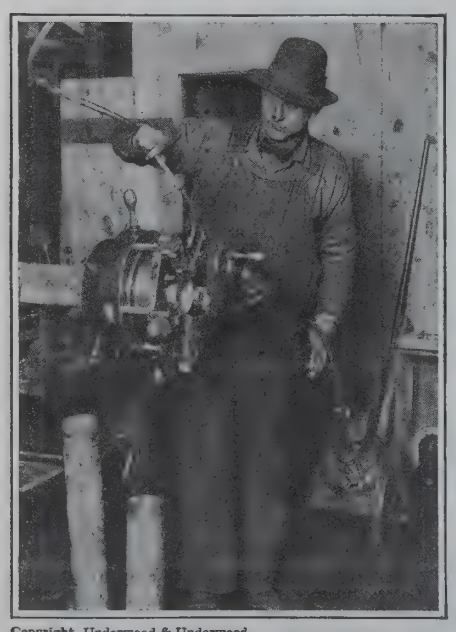
## A Canoe That Goes Anywhere

SOMEWHAT out of the ordinary is the canoe-carrying motorcycle shown in this photograph which comes to us from England. An ingenious young man, Mr. Armstrong, who served in the Royal Air Force as an experimental airman, designed and constructed the arrangement shown in this picture for the purpose of carrying his canoe to distant waterways. The canoe, it will be noted, also serves as a side car for carrying one or two passengers and luggage. An arrangement of helical springs makes this exceptional side car easy riding.

## Taking the Hard Work Out of Threading Pipe

AT best, and that means with the finest tools hitherto available, the threading of large pipes has been a slow and laborious kind of work. The necessity of doing this work "on the job" has prevented the introduction of the usual machinery, and the workers have had to cut threads with stock and dies.

Now comes a Toledo, Ohio, concern with an electrically-driven machine for threading pipe. This machine, which is shown in the accompanying illustration, is a highly portable affair so that it can be used "on the job," even when said job is a relatively small one. The machine consists of an electric motor mounted on a two-wheeled truck, a suitable transmission system which can be adjusted to work at any angle, and the screw-cutting member. It is said that a 12-inch thread which would take two hours and two men to cut by hand, is now completed with this machine in 15 minutes and with one man.



Copyright Underwood & Underwood

**Electrically-driven thread-cutting machine which does the work of two men in one-eighth the time**

## A Household Ladder That Is Never in the Way

EVERY household requires a ladder. Unlike most other pieces of furniture or equipment, the ladder is required only once in a while, but when it is required the need for it is so great that serious inconvenience results in the absence of it. Again, when it is not required, which means something like ninety-nine one-hundredths of the time, it must not be in the way.

With those facts recalled to our attention, we are ready to appreciate the ingenious ladder recently developed by an American inventor. This ladder may be completely folded up and fastened to the back of a closet door, as shown. When set up, ready for use, it is exceptionally rigid so that the housewife need not fear using it. Unlike the usual convertible chair and ladder, which, while it serves two functions, is a poor chair, the new ladder remains rigid and outlasts several of the former.

**This little ladder is exceptionally strong and rigid, yet may be folded flat and fastened behind a closet door, out of the way**

## Discovery of Iron Ore in Switzerland

THE Federal Council officially states that the Society of Study, founded in 1918 at the instigation of the Federal Department of Economics, has by explorations and excavations in the Frickthal, a valley in the northern part of the Canton of Aargau, recently discovered an area of 190 hectares (hectare = 2.47 acres) containing 15,000,000 tons of iron ore. In the immediate vicinity, not yet surveyed and excavated, there is estimated an additional amount of 22,000,000 tons. One can realize the importance of this discovery, it is stated, if it is understood that these millions of tons will assure to Switzerland, at pre-war consumption rate, sufficient iron ore to last for 45 years. The Federal Council suggests a provision by the Government of 1,200,000 francs upon condition that a total capital of 4,000,000 francs is raised for exploitation.

## A Clock That Speaks For Itself

FOR seven years Mr. H. Hartmann, a New York inventor whose name is no doubt familiar to many of our readers by reason of his several past inventions which have been described in these columns, has been using the clock shown in the accompanying illustration. So it is apparent that this clock has a rugged and lasting mechanism, and is out of the experimental class.

The clock in question is a speaking clock; that is to say, it speaks every fifteen minutes, announcing the correct time. The voice record is carried on a band of film which is perforated in much the same manner as the standard motion picture film. A conventional phonograph reproducer is used to translate the latent sound record into actual sounds. Pressing a button causes the clock to repeat the time, while another button keeps it silent. The clock is only 16 inches high, 10 inches wide, and 9 inches deep.

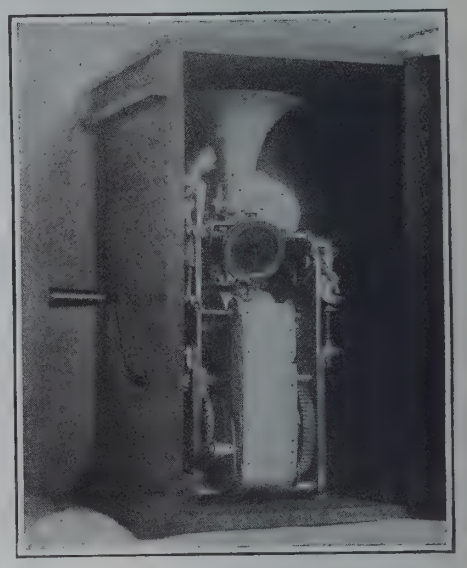
## Barrels Made of Paper

FARMERS and manufacturers have felt the ever-increasing cost of barrels, and it has been pointed out on more than one occasion that barrels are playing no small rôle in the general high-cost-of-living scheme.

For some time inventors have been at work on the barrel problem with a view to producing cheaper containers. Several of them have tackled the paper barrel problem and it appears as though their work has finally materialized into something of practical value. These paper barrels are generally made in the form of many layers of stiff paper, held together by some suitable adhesive which may also be watertight and weatherproof.

The barrel shown in the accompanying illustration is made by a winding process employing chip board, and is said to cost one-third less than a wooden barrel of equivalent size. The inventor also claims greater strength for this paper barrel.

Paper cans and other containers can be made of wound paper, and no doubt much will be done along this line in the near future.



**This clock has neither dial nor hands; it speaks the time like a phonograph**

## Commercial Aviation in England

IN the fifteenth annual report of the British Meteorological Committee plans were brought forward to secure a comprehensive service of weather reports to facilitate commercial aviation and to forecast accurately aerial conditions affecting the London-Paris-Brussels service.

The plan has in its purview the establishment of approximately 20 distributing centers, staffed by trained meteorol ogists, who will provide regular information covering the following points:

1. Wind at surface and at 2,000 feet
2. Weather (present and past in general terms).
3. Amount and height of any low cloud.
4. Visibility.
5. (For seaplanes.) The state of the sea, particularly in regard to the nature and amount of the swell, which affects the power of a machine to rise.

During the past month the Swedish post office has announced a regular air service from Stockholm to Malmo, Copenhagen, Hamburg, Bremen, Amsterdam, and London, and the service known as the London-Copenhagen Air Mail, recently inaugurated for service to London via Hamburg and Amsterdam, with Copenhagen as starting place, will accept express letters for distribution in the afternoon following the morning of departure at Berlin and Hamburg, and at night in Amsterdam, while express letters will be delivered in London at 2 P. M. on the following day and ordinary letters a few hours later.

**Eleven-gallon barrel made of paper and costing one-third as much as a wooden one**

## *"If we only had thought of that before we built!"*

TOO often such a wish occurs to the new home owner after the house is occupied. A change then is less satisfactory and more expensive. So it behooves the home planner to anticipate the electrical features that mean so much convenience, comfort, and housekeeping happiness.

A floor plug here or a switch there built in where it is needed —these are so little, so inexpensive, but so all-important.

From basement to attic, there are many places for electricity in the home. Light, heat, power—at your finger-tips, to wash the clothes, iron, sweep the floors, wash the dishes; cook the meals, run the sewing machine, play the piano or phonograph and regulate the furnace drafts. And even an electric refrigerator is a present-day possibility.

To take advantage of electricity to the fullest extent is a matter of vision or foresight. The well planned home is a fairy palace, where electricity magically removes tiresome tasks at the push of a button on the wall.

The modern architect or electrical contractor realizes how much depends on the proper installation of wiring devices, and plans accordingly. He knows what a satisfaction the housewife finds in a lighted closet, or a buzzer that tells her the light is burning in the cellar.

The General Electric Company has perfected the big electrical machinery which generates, transmits and distributes this modern power to millions of homes. It has provided the motors, lamps, heating units, and even the switches and connections necessary for complete service, and has placed these devices at the disposal of architects, builders and dealers all over the country. Thus the home builder may readily obtain the elements so necessary for complete electrical equipment of the modern home.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Pertaining to Apparel

GARTER.—P. E. ROSEN, 117 W. Main St., Madison, Wis. The invention has for its object to provide a device especially adapted for men's use, wherein the garter consists of a strip of non-elastic material having at one end a clasp for engaging the hose and having near the other a loop through which the clasp is adapted to be passed to form a sliding loop for encircling the leg at the knee to provide a support which will accommodate itself to the movement of the muscles to properly support the hose.

## Pertaining to Aviation

GIRDER AND THE LIKE FOR AIRCRAFT.—E. E. BROWN, c/o D. J. Mooney, Steel Wing Co., Ltd., 48 a Gallingham St., London, S. W., 1, England. The invention has for its object to provide a metal girder or equivalent structure for aircraft which shall be very stiff and stronger in proportion to its weight. The girder comprises composite channel members placed back to back, characterized by the web portion being provided with parallel ribs which are set obliquely to the longitudinal direction of the girder, the ribs of one channel member being sloped in the opposite direction to those of the other which increases the parallel resistance.

METAL CONSTRUCTION.—E. E. BROWN and D. J. MOONEY, c/o The Steel Wing Co., Ltd., 48 *a* Gillingham St., London, S. W. 1., England. The invention relates to a metal frame device for use in connection with airplanes. An object being to provide a spar composed of sheet metal which will embody the maximum of strength and at the same time be as light in weight as is possible consistent with the use.

## Electrical Devices

RELAY ARMATURE.—J. I. MITCHINER, 78 S. Pryor St., Room 401, Atlanta, Ga. An object of this invention is to provide a telegraphic relay armature of such a construction that two or more electrical contacts are simultaneously made in separate circuits upon the energization of the relay magnet. Another object is to provide an armature by which the making of one contact in each of two separate circuits simultaneously is enabled to be made without the aid of supplementary springs.

DEVICE FOR ATTACHING ELECTRIC LIGHT FIXTURES TO OUTLET BOXES.—R. BATTLE, Box 859, Okmulgee, Okla. This invention has for its object to provide a device of the character specified, so constructed that the fixture, as for instance a light or fan, may be readily removable for inspection, repair, interchange, cleaning and the like, and adapted for use on either ceiling or side wall.

LAMP FIXTURE.—J. S. PENNEFATHER, 500 W. 144th St., New York, N. Y. The invention relates more particularly to an adapter used for the purpose of converting a vase into a base for supporting an electric light and shade fixture. An object is to provide an adjustable adapter to fit various forms, shapes, sizes, and heights of vases, which may be readily mounted upon a vase, and which will be ornamental in appearance.

## Of Interest to Farmers

CULTIVATOR.—R. L. GUTHRIE, R. 3, Box 409, Santa Rosa, Cal. This invention relates particularly to hand-operated cultivators of the wheel type, an object being to provide means for connecting the standards and braces of the structure to the frame supporting the same, whereby the parts may be easily and quickly adjusted or rearranged to perform the desired functions.

MAIZE OR INDIAN CORN HARVESTING MACHINE.—E. LOGARZO, Buenos Aires, Argentina. The invention is characterized by the special construction and arrangement of the husking means constituted substantially by a pair of biconical cylinders placed at an angle, and the surface of each of which is grooved or fluted in parallel direction of its axis, or in a helicoidal direction. The movement of the machine is obtained by means of a gearing driven by the axle of the transportation wheels.

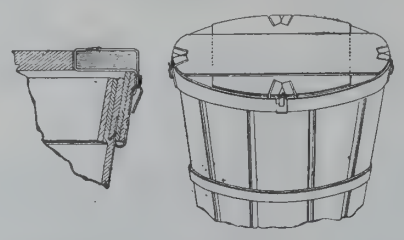
## Of General Interest

LIFEBOAT.—G. DORFFEL, 2141 S. 47th St., West Seattle, Wash. The invention relates to lifeboats or escape buoys for use with submarine vessels. The object is to provide a device which can be easily and quickly launched, which is carried in position by the submarine vessel so that interior access can be had at all times before launching, and which will not unfavorably affect the normal operation or maneuvering of the submarine vessel.

COFFEE POT.—W. H. BRUNING, 100 Upper 1st St., Evansville, Ind. Among the objects which the invention has in view are to avoid radiation of heat during the process of making coffee, and of radiation of heat from the coffee subsequent to the making thereof, to distribute water poured over the prepared coffee, to equalize the filtration thereof, to provide means for maintaining by diffusion the heat of the liquid coffee, and to construct a coffee pot arranged to afford easy access for the purpose of cleaning.

PRODUCT IMITATING CHINA.—C. BUTTY, Calle Maipu 671, Buenos Aires, Argentina. This invention is adapted to be used as an imitation of china, marble and the like; it is not affected by acids or changes in weather, and in consequence is particularly suitable for the manufacture of buttons, insulators, objects of art, etc., and other articles not destined to get in contact with fire. The composition is as follows: Sulfur, 40 per cent; clay or Roman cement, 60 per cent, and a coloring matter.

BASKET FASTENER.—J. F. KENNEDY, 9 Laurens St., Charleston, S. C. The invention relates generally to fruit and vegetable baskets and more particularly to the fastenings thereof, an object being the provision of a



A PERSPECTIVE VIEW OF BASKET WITH COVER SECURED

simple and inexpensive means capable of ready use without the necessity of driving fasteners in the basket cover, as well as a fastener which may be speedily applied and will be effective in use.

COMBINED PERISCOPE AND GUN.—L. HOLECEK, 652 7th Ave., Oakland, Cal. An object of the invention is to provide a combined periscope and gun for submarines, to permit of accurately swinging the gun to correctly aim the gun at a distant object as seen through the periscope. Another object is to permit of firing the gun when the submarine is in submerged, raised or awash position, and to permit the gunner to swing the gun up or down to obtain the desired elevation or depression.

PURSE.—W. STONE, 66 W. 36th St., New York, N. Y. An object of the invention is to produce a coin purse made in conjunction with a hand bag and thus combining the advantages and facilities of both, a large hand bag and a small coin purse. One of the primary objects is to provide against the necessity of carrying both hand bag and coin purse in order that a lady may be equipped with an article which will materially facilitate the payment of car fares and other small change in crowded places.

## Hardware and Tools

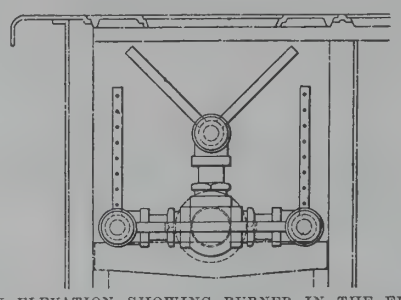
MILLING CUTTER.—W. A. JAMES, c/o Ellis Spear, Jr., Tremont Bldg., Boston, Mass. A specific object of the invention is the provision of a milling cutter in which certain of the tool elements are set at an angle to the axis of rotation, while others are parallel with the axis, so that when the disks are moved axially, one with respect to the other, all the disks are effectively clamped or unclamped.

CENTERING PUNCH.—H. M. WALKER, Benford, Texas. This invention has for its object to provide a device having means for permitting the punch to be accurately centered in an opening of a pattern plate for instance, to insure that the punch will engage the work at the exact center of the opening, and wherein the punch is adjustable for openings of various sizes.

OVERSHOT.—R. A. DAILEY, c/o Honolulu Cons. Oil Co., Taft, Cal. The invention has for its object to provide a device adapted for fishing broken tools from a well casing, wherein a body portion is provided having slips or dogs for engaging the tool to hold the same, together with various types of interchangeable bowls for facilitating the engagement of the overshot with various characters of break.

## Heating and Lighting

GAS BURNER FOR HEATERS.—R. DEPEW, 1485 DeKalb Ave., Brooklyn, N. Y. The object of the invention is to provide a gas burner for use in the firebox of a kitchen range, house-heating furnace and similar heater, and arranged to insure the production



AN ELEVATION SHOWING BURNER IN THE FIREBOX OF A KITCHEN RANGE

of a high heat with an exceedingly economical consumption of gas. Another object is to provide a gas burner of simple construction which can be readily installed in a firebox without requiring alteration of the same.

## Machines and Mechanical Devices

COAL HANDLING MACHINE.—E. N. WEAVER, 98 Columbus Ave., Jersey City, N. J. Among the objects of the invention is to provide mechanism for rapidly handling, sizing, and transferring bulk material such as lump coal in regulatable quantities from one ship or conveyance to another, as for instance, in the rapidly coaling of ships through a chute into the lumber hatch, thus dispensing with the necessity of employing many laborers.

CARGO HANDLING APPARATUS.—J. G. GUNN, Cherokee, Iowa. An object of the invention is to provide a cargo handling device by means of which cargoes may be quickly and easily transferred from place to place and the cargo dumped or unloaded expeditiously in any place and manner desired by the mere operation of a crane or other lifting device employed.

STEAM CIRCULATING BY-PASS AND RELIEF VALVE.—E. B. WHELAN, 1025 S. 10th St., Omaha, Neb. The invention relates generally to valves for steam engines, especially locomotives and particularly to valves which function as by-pass and vacuum and compression relief-valves, the object being the provision of an arrangement whereby low pressure steam is positively circulated through the cylinders when a locomotive is drifting for the purpose of lubrication, in addition to the usual functions of a valve of this type.

MOTOR.—J. SCHROEDER, 1624 W. 7th St., Davenport, Iowa. An object of the invention is to provide a valve gear comprising a shaft and means for turning the shaft in opposite directions, a crank disk loose on the shaft, means for compelling the disk to turn with the shaft during a portion of the rotary movement in both directions, a spring operatively connected to the disk and compelling the latter to complete its movements, a valve operating crank arm, and a rod connecting the disk and crank arm.

## Musical Devices

SOUNDING BOARD FOR MUSICAL INSTRUMENTS.—J. VIRZI, 341 E. 124th St., New York, N. Y. The invention has particular reference to sound boards for such instruments as violins, violas, cellos, pianos or the like in which there is ordinarily used a sound board as a means amplifying the sound vibration. Among the objects is to provide an auxiliary sounding board arranged in spaced relation to the main sounding board of the instrument and having the periphery thereof disconnected from all other parts of the instrument.

ARTICULATOR FOR PHONOGRAPHS.—F. B. LONG, 833 Market St., San Francisco, Cal. The object of the invention is to provide the sound chamber of a phonograph into a sound board of a highly vibrant material and subjected to edgewise pressure to form a crown on the sound board with a view to insure perfect vibration. Another object is to throw back upon the sound board the molecular vibrations emanating from the sound board.

## Prime Movers and Their Accessories

ATTACHMENT FOR INTERNAL COMBUSTION ENGINES.—W. E. STITZER, Box 299, Muskogee, Okla. The object of this invention is to provide mechanism for use in connection with lubricator and controller by the level of the oil in the lubricator, for stopping the motor when the oil falls below a predetermined level, by short circuiting the ignition system.

VALVE SPRING COMPRESSOR.—F. E. JENKINS, 121 Kenwood Ave., Medford, Ore. The invention relates to tools for compressing valve springs of automobiles, airplanes, or other gasoline motors; its object is the provision of a device adapted to be engaged upon a valve spring to be compressed and so constructed that after the device is initially set in position it will automatically compress the valve spring.

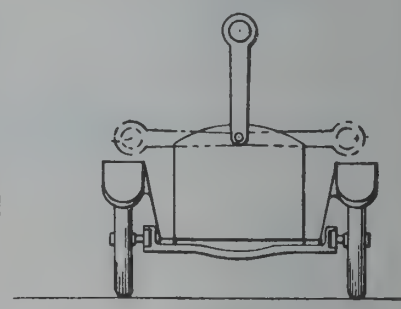
## Pertaining to Recreation

PLEASURE RAILWAY.—M. JOHNSON, 249 56th St., Brooklyn, N. Y. Among the objects of the invention is to provide a pleasure railway for parks, exhibition grounds, fairs and other places of amusement, and arranged to accommodate a large number of persons at a time, and to provide an exhilarating ride for the participants. A further object is to provide a pleasure railway which is simple and durable in construction and safe in operation.

TOY.—E. W. TRAUTMAN, Gulfport, Miss. The invention has for its object to provide a device wherein the toy has the outline of a vessel, as, for instance an airplane, torpedo, or ship, and is provided with a supporting pulley adapted to run upon a cord to which the toy is swiveled, the toy having guiding vanes and a propeller, and means for exploding a torpedo when it strikes an obstruction.

## Pertaining to Vehicles

DIRECTION INDICATOR.—J. E. MAYHALL, 1216 Madison Ave., Covington, Ky. The primary object of the invention is to provide a convenient means for facilitating driving a vehicle, preferably a motor vehicle in a congested city or in fact anywhere it is desira-



A FRONT VIEW OF VEHICLE WITH DEVICE ATTACHED

ble to give a warning to a vehicle either approaching from the front or rear, the direction which the vehicle or which the indicator is installed is to take, the device being conveniently operated by the chauffeur.

TIRE HOLDER.—A. F. ENGEL, 650 Wayne Ave., Defiance, Ohio. An object of this invention is to provide a tire holder such as is commonly carried on motor vehicles and which permits ready insertion or removal of the tire. A further object is to provide a holder which can be swung to one side to provide a free entrance or exit for the tire, and which when moved into position and locked, will securely hold the tire against accidental movement.

## Designs

DESIGN FOR A KNIFE SHARPENER.—T. C. CURLEY, 87 Duane St., New York, N. Y.

DESIGN FOR AN ARTICLE OF MANUFACTURE, NAMELY, A PILLOW OR ARTICLE OF A SIMILAR NATURE.—M. D. DREYFACH, 482 Broome St., New York, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## The State and the Farmer

(*Continued from page 494*)

details of farm improvement and farm methods have been carried out under the advice of the Board's experts, free to the settlers. Nothing in the community has been done in a loose or haphazard manner and under this *modus operandi* a model farm community was evolved in less than one year.

In the meantime practical farm development was taken up, soil maps consulted, fields, orchards and gardens laid out, and crop production arranged. The Board has made itself the friend and counselor of each settler, and has been unstinting in advice as to the planting of crops, purchase of live stock, tools, equipment, seed, etc. It also gave valuable advice in the organization of coöperative buying and selling organizations among the settlers; the construction of an extensive scheme of roads, drains and irrigation works; as well as advising the farmers as to the best methods of leveling, checking and smoothing their lands and the preparation of seed beds and the planting of seed.

In order that no time be lost in the production of crops the first year the Board helped the farmers by having a big outfit to prepare land for seeding and irrigation and actually to put in crops of barley, oats and wheat, taking the pay for the work out of the crop.

Here are some of the net returns to individual settlers from some of these crops: C. W. Baker, fifteen acres of oats, $105; E. O. Messenger, eighteen acres of barley, $368.28; William Deveney, 20 acres of barley, $66.10; Carl Neilson, eighteen acres barley, $476.75; A. I. Maxwell, 12 acres barley, $313.40; E. E. Will, 47 acres barley, $696.38; Jos. N. Thornton, 54 acres wheat, $624.50; Frank M. Hall, 47 acres barley, $955.15; Roy White, 60 acres barley, $1,390.50.

The survey and mapping of the settlement land were based largely upon the story told by the soil map. Samples of soil were taken at such intervals as was necessary to make an accurate map of the whole area.

With this in hand the sizes of the farms were determined so as to give considerable choice to intending settlers, keeping each farm within such limits that one family, with the help of one farm hand, could take care of it.

Consequently the farms suited to fruit-growing were made small, while the lands suited to farm crops were laid out in larger units, running as high as 160 acres. In some cases a tract of grain land went with a small tract of fruit land, say, 15 or 20 acres, the two tracts sometimes not being contiguous.

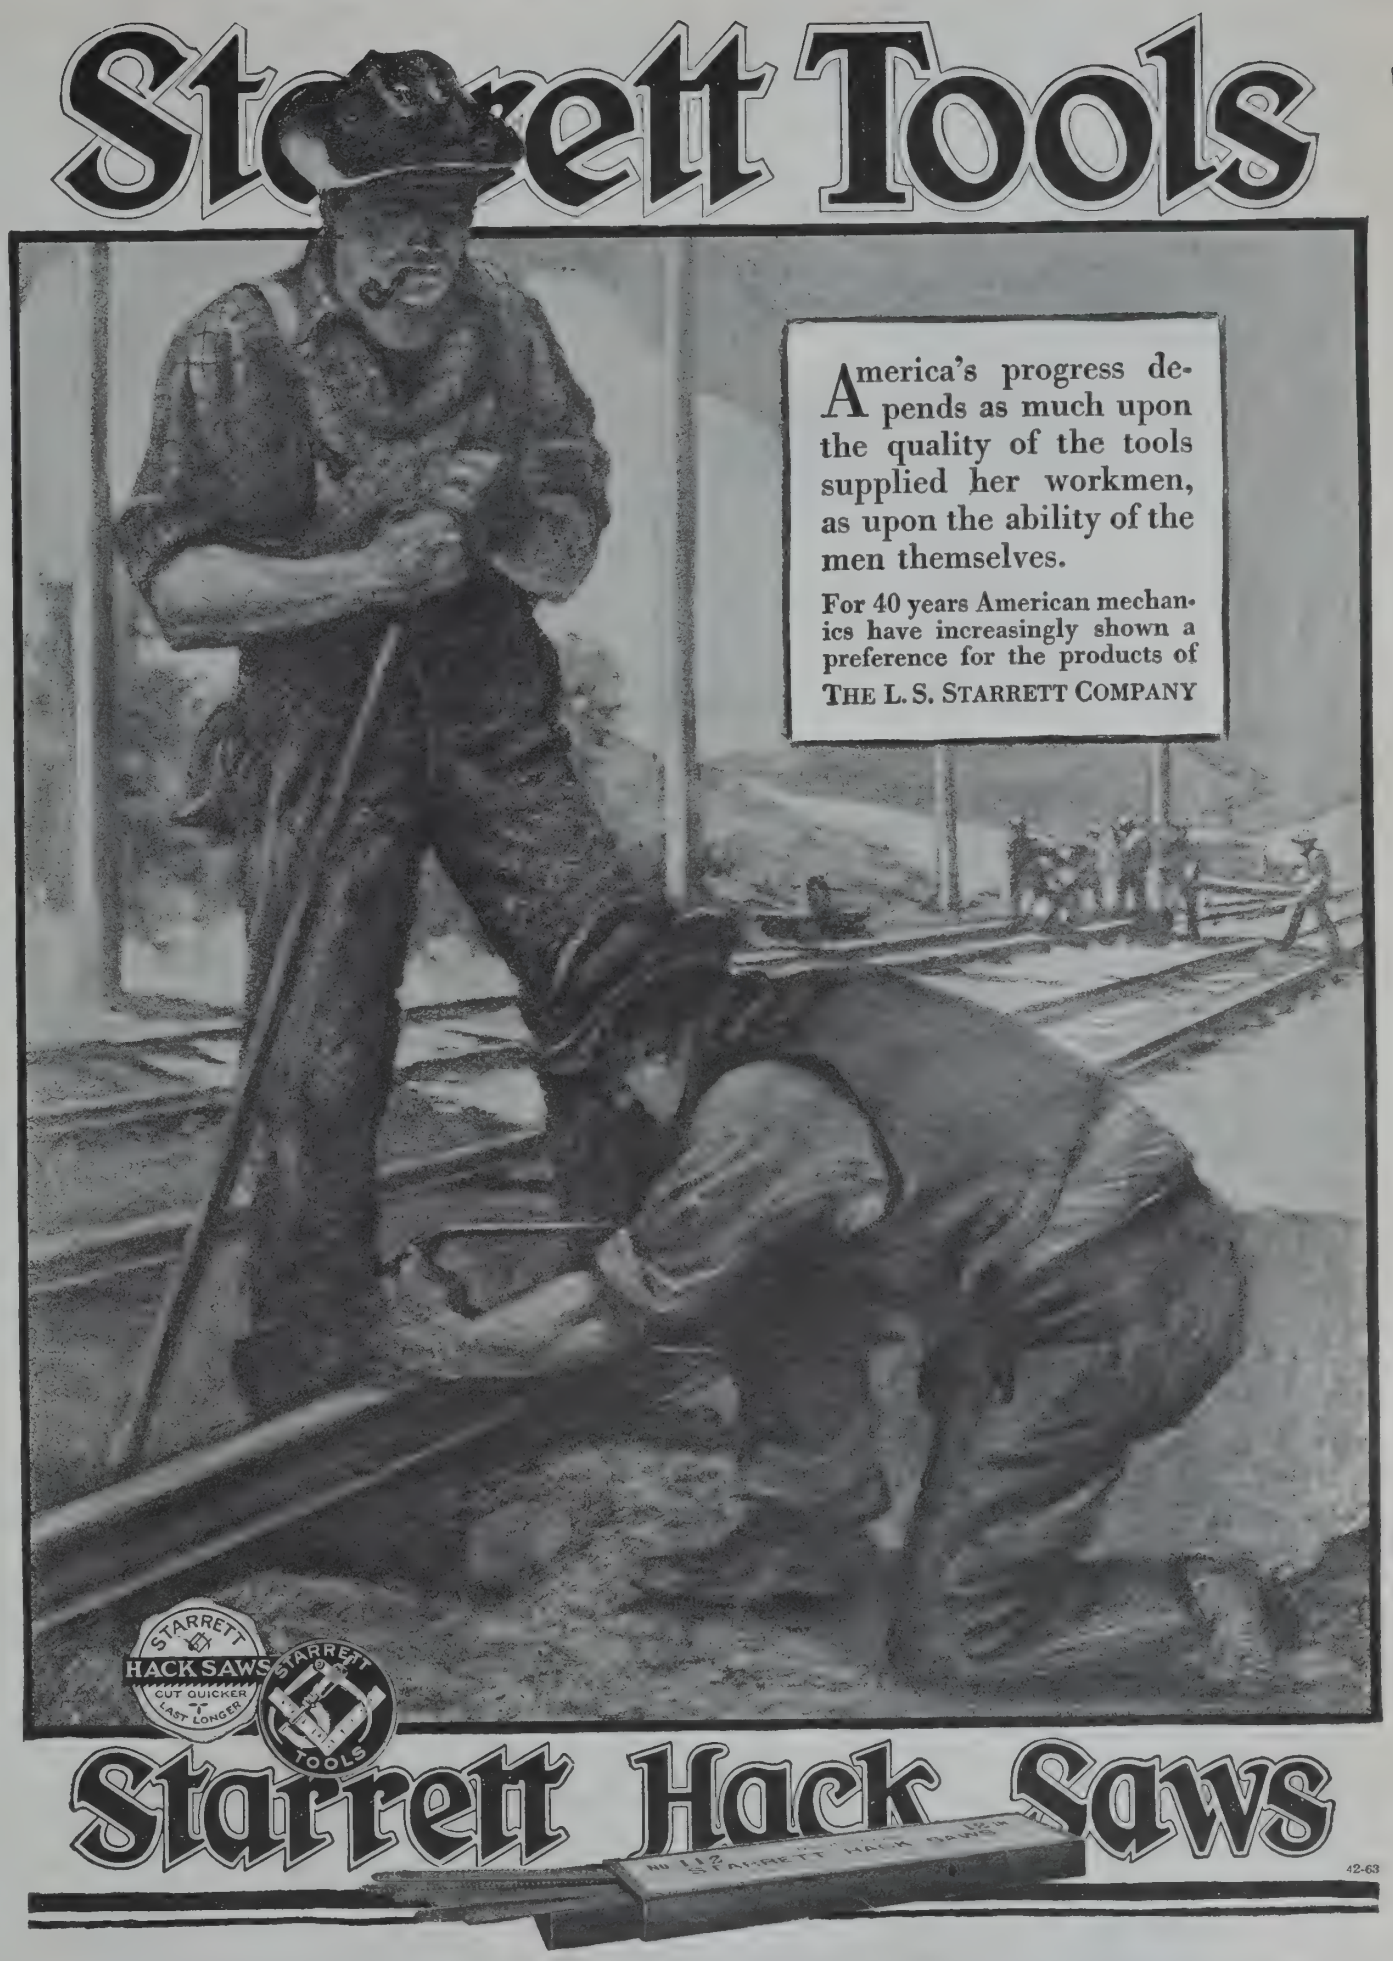
The State Land Settlement Board was not insensible to the social needs of the community, consequently it set aside a fine tract of 22 acres as a community center. It is planned to erect upon this plot a community hall where different social and business organizations will find meeting room. There will also be laid out and equipped athletic grounds where the boys may play baseball and the girls lawn tennis. Upon this community center is a fine grove of native oaks where picnics are held. It is also the intention of the board to establish on these grounds a vocational school.

Thus Durham has been made a model rural community. It is benefited not only by the paternal influence of the State but by the fraternal character of the settlement.

The State not only supplies financial backing for the settlers, but it educates them in the most up-to-date farm practices. It has inaugurated both a system of collective buying and of collective selling, thus insuring the settlers against the wiles of sharpers and profiteers.

The settlers themselves become imbued with agricultural ambition and pride. The close intimacy of the settlers begets a common feeling of fraternity.

The concentrated nature of the popu-



### Selecting the Right Make of Hacksaw

"As the saw, so is the reputation of its maker. Nothing but the best in composition of material, heat treatment and the greatest accuracy in cutting, spacing and setting the teeth will give the best results, no matter how skillfully the blade may be used. And, vice versa, no matter how high the quality of the saw, economy of or in operation cannot be secured if the blade is put to uses other than those for which it was intended by the maker, or if certain fundamental facts are overlooked."

### The Essentials of an Efficient Saw

In selecting a Hack Saw, three objects should be kept in mind:

(a) The blade must cut fast.

(b) The blade must do the maximum amount of work at the minimum combined cost of the saw itself and the labor and overhead chargeable to the operation.

(c) The blade must be suited for use on the largest variety of materials possible without interfering with "a" and "b."

### A Practical System of Blade Selection

"Any system of blade selection to be really practical must be based wholly on the material to be cut, rather than on any classification of blades according to a list of trades or an arbitrary classification by number. Were it possible to say that in any particular trade only certain classes of material were cut, such a classification would be ideal; but, dividing the metals according to their influences on cutting speed, saw life, etc., which is the only true basis to use, it is practically impossible to say that any given trade will have occasion to cut only a definite portion of the list. Efficiency is best served by classifying the various materials, the one group of factors with which every operator, skilled or unskilled, is familiar, and putting opposite the name of each metal the catalog number or designating letter of the saw which should be used.'—from Hack Saws and Their Use, published by The L. S. Starrett Co., Athol, Mass., for free distribution.

lation works for friendliness and sociability, and thus the proverbial dullness of ordinary rural life is done away with and the life of the farmer seems less irksome and burdensome, all of which inures to contentment, happiness and prosperity.

Acting upon the recommendation of Governor Stephens the California Legislature of 1919 appropriated $1,000,000 for continuing the land settlement system, and also authorized a bond issue of $10,000,000 for a like purpose. Under these provisions the State Land Settlement Board has purchased a 10,000-acre tract of farm land in Merced County in the central part of the San Joaquin Valley for settlement in the near future, along similar lines as those governing the Durham settlement. In the settlement of this second tract preference will be given to ex-service men.

## Winter Fuel from Our Woodlands

(*Continued from page 495*)

eastern part of the United States, the owners of those woodlands will not cut and market the wood unless they can sell at a profit. Ordinarily, cordwood is sold only in a district within 5 to 10 miles from where cut, and hauling is done direectly from the cutting area to the purchaser, but where water or railroad transportation is easily available it is possible for the farmers to cut their wood and ship it several hundred miles at a profit.

Cordwood is ordinarily cut into 4-foot lengths, and with a power saw run by a tractor or gasoline engine, a three-man crew can saw up from 10 to 15 cords per day. Splitting is either done by hand or by machinery, for in recent years several types of splitting saws have been invented and it is possible to saw and split the logs by the same crew.

The cost of hauling wood by team will average from 50 to 75 cents per cord per mile, which restricts the area of delivery to a small radius. When shipped by rail, the freight rate for distances of about 10 miles will average from 50 to 60 cents per cord, while the same wood can be shipped a distance of 100 miles by rail at a cost of from $1 to $1.50 for freight. Water rates are, of course, very much cheaper, and by far the larger portion of the 17,000 cords of wood fuel used annually by the City of Washington is brought up the Potomac River on sailing vessels, carrying an average of 30 cords and requiring but two or three men to operate. In loading or unloading from cars or boats one man can handle from 7 to 10 cords of 4-foot wood per day and from 6 to 8 cords of 16-inch wood.

In attempting to solve the fuel needs of communities, various plans have been devised to bring the producer and consumer together. In a number of cities municipal wood yards have been established, where fuel can be brought for sale. One New England city, which was hard-hit by the fuel shortage two years ago, arranged for the purchase and storage of 100,000 cords of farm wood, to be used as a fuel reserve, and in a Southern State there are more than 30 municipal wood yards in operation. A yard established at Durham, N. C., purchased 1,260 cords of wood at an average cost at the yard of $5 a cord, and was delivered to the consumer at an average cost of $7 per cord. The material was obtained from two sources, one, consisting of slabs, from a sawmill about 14 miles distant, and green pine and oak from farm woodlands near by. The slabs, of odd lengths, were purchased from the mill for $2 per cord f.o.b. cars, and were unloaded at the municipal yard, where they were cut up into desired lengths. The freight charges on these slabs amounted to 75 cents per cord. The wood from the farmers' woodlands was cut in 8-foot lengths and split in halves or quarters. The price was $3.50 per cord piled in the woods. It was hauled from the woods to the roadside by country teams, and motor trucks carried it from the roadside to the yard, and the total cost of hauling was about $1 per cord, for the distance of 3 miles from the cutting area. The cost of cutting the wood into stove lengths at the yard was about 50 cents per cord.

A standard cord of firewood is a pile 8 by 4 by 4 feet, or 128 cubic feet of stacked wood. A pile of green wood will shrink two or three inches through settling and drying, and it is customary to pile green wood somewhat higher than 4 feet to allow for this shrinkage. A running cord, or "face" cord, 8 feet long by 4 feet high and 12, 16 or 24 inches wide, according to the length to which it is cut for use, is frequently called a cord in the market. Though a cord contains 128 cubic feet the space occupied includes air as well as wood, and the actual wood content is only about 70 per cent of this amount, or 90 cubic feet of average size. Small, smooth sticks pile closer together, and therefore there is less wood in a cord of crooked sticks than a cord of straight sticks.

## Forewarnings About Forest Fires

(*Continued from page 495*)

Sparks from railroad locomotives which traverse timbered country also cause many destructive forest fires each year. This is displayed by means of a miniature passenger train which runs along the foot of a mountainous slope which is heavily forested. Sparks from the engine fire the underbrush and rapidly the flames climb the hillside. Similarly, fire damages caused by motor tourists who throw lighted cigars, cigarettes or pipe ashes from the automobile as it speeds through a densely timbered territory are also depicted in the mechanical exhibit. These sparks touch off the dry refuse on the ground and directly the flames spread over the adjoining hillsides. From a scientific and mechanical standpoint this novel method of illustrating forest fire causes is extremely meritorious and praiseworthy. Wherever it has been exhibited it has elicited much favorable comment and has resulted in many careless motorists, campers and ranchers reforming their activities as related to camp fire neglect, match use and ignited tobacco disposal.

## Solving the Labor Problem—II

(*Continued from page 496*)

through our classes we help the man train for the job ahead. We point out that we fill our big jobs from the inside, and point out the men at the head who started low. What's more we stick by that policy.

After a man has been with us a month, he receives from the Employment Office a questionnaire headed "Application for Promotion." This outlines our policy of filling big jobs from the inside and asks the man what he is doing to prepare himself for promotion. It asks him what he wants to make of himself, and what he is doing to attain that end. When this is filled out and returned we have a fairly good line on the man and are in position to help him help himself.

We have done two things by this: First, we show him that we are interested in his development and look upon him as the sort of man who wants to stick with us. Second, we have gotten a pretty good analysis of the man, his ambitions, and his possibilities. These questionnaires are filed, together with a man's class record, and are consulted when promotions are being considered.

When you combine work of this sort with an absolute policy of square dealing you have a good basis for labor relations. When you realize that the men who work to build your product must be sold on the plant and its policies, just as your customers must be sold on your product and your policies, then you will have progressed a long way on the road to harmony. Men want to be treated as men. They want you to hear what they have to say about the policies under which they

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

C. H. VOORHEES, Box 405, SO. LAKE WEIR, FLORIDA

work, and, more than all that, they want to know that you are with them and look upon them as individuals, not accessories to machines.

Now for the pessimism. I always like to include a bit of warning along with the cheerful news.

Don't think that because someone has a plan that works that you can lift that plan and have it work as well for you. It isn't the plan that does it, it's the spirit. Plant spirit cannot be created over night. It does not come as the result of anything but long, hard work on the part of somebody who deliberately lays out a campaign for it.

In our case our campaign of education was running for more than a year before we said anything about any system of employee representation. Our plan came as a factor in a whole campaign to have men understand what they were doing and why. Never has it dominated the situation and we hope it never will.

Your work is never done. Almost every week we have some pamphlet to pass out. We are keeping at it constantly. We believe that the more education a man gets, the more he wants, and we aim to keep him supplied with all the information available on timely subjects.

Remember your workers are the same as you are. They respond to the same treatment that you respond to, and recoil from the same sort of treatment that you would recoil from. Get out in your shops and meet them. Let them meet you. They'll add considerably to your knowledge and you can be of great assistance to them. Tackle this subject together. Tell them what they want to know about the business and let them see the basis under which capital and labor are working in your plant.

Men would rather accept information from you than misinformation from an agitator. The trouble has been that hitherto the agitator has had no competition from those who knew the facts but would not pass them on.

The time has come to change this. Business must sell itself to those who help make it. The workers must be appealed to on the basis of education.

Give your men facts to think with and they'll see the pitfalls in destructive theories.

## Fuel or Fertilizer?

(*Continued from page 498*)

legume crops because when introduced into the soil the proper bacteria to suit the conditions become active. Such inoculants form part of the product of these peat plants. A two-pound can is sufficient to inoculate an acre of ground.

The more general practise, however, is to make of the peat a commercial fertilizer and to inoculate this fertilizer with the bacilli before it leaves the plant. Thus is produced a product that is at once a fertilizer and an inoculant and in addition other strains of bacilli are added which generate plant foods from the decaying vegetable matter in the soils. The result is very nearly a "universal" fertilizer, for there is hardly any soil condition or plant growth that cannot be improved by its use.

It is difficult to say how long peat has been used in making manure. A little book published in 1815 by an anonymous author is entitled "Directions for Preparing Manure from Peat." It seems the author was a wealthy Scotch landowner. Having occasion to excavate a small peat bed in building a lake, he was at a loss to know what to do with the muck. His Scotch thrift, no doubt, suggested the idea that it might make a good fertilizer and he began a series of experiments in a truly scientific spirit. After several years he decided that the best manure was made by mixing common stable manure with about double the quantity of peat, and letting it stand, mixing occasionally. He found that the decay in the peat was apparently communicated to the

PHOENIX HIGH GRADE REFRIGERATING EQUIPMENT
CLEVELAND, O.
March 25, 1920,

Ever-Tight Piston Ring Co.,
Kingsland Ave.,
Wellston, St. Louis, Mo.

Gentlemen:

It has been the policy of this Company not to issue any testimonial letters until we have given the various products which we use in connection with our equipment, at least 12 months trial.

We are, however, pleased to state that we have been using Zelnicker Everfyte rings for two years and during this time have found that they have been giving perfect satisfaction in every respect. We have adopted your ring as standard and are glad to recommend them to others who are in need of a good efficient ring.

Yours very truly,
THE PHOENIX ICE MACHINE CO.
Mgr.

The distinguishing fact about the Zelnicker Ever-Tyte Piston Ring is its invariable acceptance by engineers on their own operating tests.

The superiority of this ring in economy and efficiency is so *marked* in actual use, as to justify the discarding of ordinary ring equipment, even in new units, for the installation of Ever-Tytes.

The economies effected with Ever-Tyte Rings are past the stage of questioning or comparison. Eight years accumulated records present the *proof*.

That evidence covers the use of Ever-Tyte Rings in steam and gas engines, compressors, ice machines, pumps, etc., trucks, tractors and autos.

Send your order for Ever-Tyte Rings and make an actual operating test. In no other way can you really credit the unusual performance of this ring.

ZELNICKER Ever-Tyte

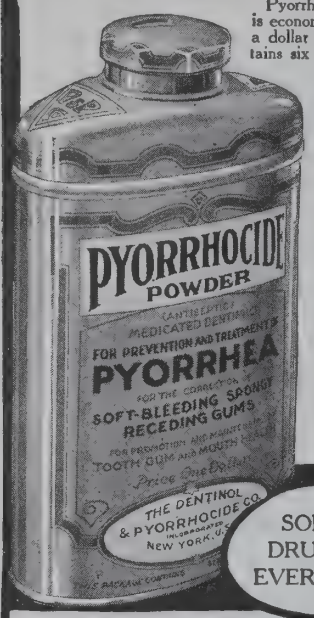
PYORRHOCIDE
POWDER
ANTISEPTIC
*for Pyorrhea prevention*

**Tender, Spongy Gums**

and gums that bleed easily, are the first symptoms of pyorrhea. If these conditions are not corrected, loss of teeth may follow.

Pyorrhocide Powder is the only dentifrice whose value in treating and preventing pyorrhea has been proved by dental clinics devoted exclusively to the prevention and treatment of pyorrhea. Pyorrhocide Powder's specific purpose is to restore and maintain gum health, but it also cleans and polishes the teeth. Dentists everywhere prescribe it.

Use it daily for healthy gums and clean, white teeth.



Pyorrhocide Powder is economical because a dollar package contains six months' supply. Sold by leading druggists and dental supply houses.

EXCELSIOR

**BESSEMER OIL ENGINES**

IT requires no mechanical or engineering skill to operate a Bessemer Oil Engine. There is nothing complicated about its construction, nothing to get out of order. Burns low-grade fuel oils, a further factor in its low upkeep. And service branches located throughout the country make Bessemer Service a permanent asset to all Bessemer users. 15 to 180 H.P. Write for catalog.

THE BESSEMER GAS ENGINE CO.
14 York Street, Grove City, Pa.

manure and that he very quickly had a product which gave results superior to the manure alone.

It is rather curious to note that although the Scotch landlord's advice was apparently forgotten, the same method is recommended to farmers by agricultural experts today. Hundreds of farmers have a supply of such fertilizer available but have made no use of it.

Indeed, a peat bog is often the most valuable part of a farmer's acreage, but it is a common sight to see land cultivated up to the edge of a swamp and the swamp itself neglected. In spite of the fact that our peat resources are almost untouched, the bogs are already producing most of our commercial crops of celery and onions and a large part of such crops as carrots, lettuce, cabbage, horseradish, peppermint and cranberries.

The methods used at a peat plant at Alphano, N. J., one of the largest in the country, illustrate modern methods of production. The bog here consists of about 1,500 acres and the deposit varies from two to twenty feet in depth. The land was a marsh until reclaimed by a drainage system.

The first step in the process is to till the land. Great crops of celery are raised here every year. The plowing and disking of the soil in farming it sun dries the surface and cultivation during the season kills off the weeds so that there will be no weed-seeds in the finished product, while lime is added to "sweeten" the soil. At the end of the season about three inches of the top soil, which is then dried to a moisture content of about 65 per cent, is scraped off and piled in great storage heaps near the plant.

The soil scraped off is then replaced by a specially designed machine which digs up peat with a chain bucket, shreds it, and then scatters it by means of a powerful blower. Thus after each crop the area of the bog is cut down a little by slicing away the sides to cover the top. This machine is shown on the cover of the present issue.

The peat goes through a general conditioning process in the storage piles and the bacteria are added to it here. When the peat is taken into the plant it is first passed through a set of spiral knives, operating like a lawn mower blade, which reduces the peat to a very fine granular form. The potash and other chemicals are added in a mixing machine and the peat goes through a final process of drying in huge mechanical dryers. Great care is taken not to overheat the mixture so that the bacteria are not injured.

This final drying has a double purpose. By reducing the moisture content a considerable saving in freight is effected in shipping the product in bags, and the peat is rendered more absorbent. Fertilizer is often applied with the grain drill along with the seed at the time of planting. A fertilizer for this purpose must be finely pulverized and must flow freely. The peat has the ability to absorb so much more moisture than the atmosphere can possibly give that it does not become soggy. Once the fertilizer is in the ground this absorbent quality causes it to act as a sponge in absorbing and holding water and it is a protection against drying out the land.

Part of the peat, which is sold to other manufacturers of fertilizer, is dried out very thoroughly before leaving the plant and it does not undergo the conditioning processes.

The growing popularity of peat fertilizer in the last few years has been largely due to the fact that many nitrates, which had hitherto been available for fertilizer, were used in making explosives for our army and navy. Most of the ammonia formerly used in fertilizer, the scarcest and most expensive of the ingredients, used to come from the tankage or waste of the great packing houses. But ammonia has advanced in price so that it is no longer profitable to use it for fertilizer.

Peat has its own natural supply of ammonia and because it is put there by nature it is distributed more perfectly than could be done by the best of mixing machines. Peat fertilizer has the advantage over chemical fertilizers that all of the chemicals are not immediately soluble. About one-third of them are at once available as plant food but the rest are released only through decay and the activity of the bacteria. The fertilizer hence remains effective for about five years after it is applied.

The new-born industry has been greatly aided by the American Peat Society, organized in 1907. The society now has some 300 members, with offices at 17 Battery Place, New York City. Its officers serve without pay. The society publishes a quarterly journal which includes original papers of practical experience, abstracts from contemporary literature and patents, and descriptions of the latest uses for peat, etc.

Although certain parts of Europe have used peat for fuel for many years, due to a lack of coal deposits, the annual consumption there now totaling about 10,000,000 tons, it is only recently that European peat manufacturers have recognized a common interest and have begun organization. The "Union des Tourbiers de France" has just been organized in Paris.

Because of this world-wide reawakening in the industry itself, as well as the widening scope of usefulness for the product and the great advancement in the science, we may expect to hear more and more of peat in the years ahead.

## Gas-Tubing Tests

(*Continued from page 499*)

(G) An all-metal end-piece screwed into the tubing; a very satisfactory connection where it is not necessary to connect and disconnect frequently. In attaching to an appliance care must be taken not to get the threads crossed.

(H) Tubing is glued into rubber end-piece directly. The strength of this type of attachment is usually small and leaks are very frequent with it.

(I) Metal tail-piece is screwed into end of tube and is held in rubber end-piece by corrugations which fit corresponding corrugations in the rubber. This is usually a satisfactory method of attachment.

## "Tennessee"—Our Latest Battleship

(*Continued from page 501*)

The "Tennessee" and "California" are the last ships that we shall build carrying the 14-inch gun. The next class, consisting of four vessels, the "Colorado," "Maryland," "Washington" and "West Virginia," will be about 1,000 tons larger than the "Tennessee"; but otherwise, so far as general appearance is concerned, will resemble her. The principal difference will be that eight 16-inch guns will take the place of twelve 14-inch guns, and that a great weight of protective armor will be employed.

## First Aid for Inventors

(*Continued from page 502*)

tions of the committee provide that it shall investigate "any subject referred to it by the institute or by any of its sections," or, by a majority vote of the members present at any stated meeting, it may investigate any subject presented on motion of a member or by application. The method of procedure for the unknown inventor to enlist the services of the committee is to write to Dr. R. B. Owens, Secretary of the Institute, stating what he has to offer and requesting an application blank. This is issued when the Secretary, through correspondence, is convinced that the appliance or process has merit.

The application blank contains the following questions which must be answered:

1. What is the specific purpose of this invention?
2. What is the condition of the prior art in this regard?

**"Clean! Thoroughly Clean"**

That's what you will say when you use Goblin. This soap—a combination of the purest and most effective ingredients—dissolves every particle of dirt. It frees the pores of grease, grime and stain. When through washing with Goblin your skin is fresh and smooth and clean; a thoroughly clean skin means a healthy skin.

Always keep an extra cake of Goblin on hand for the dirty, grimy job; it'll do the work where other soaps fail.

Go to your grocer and buy a cake of it; test it to the limit; there isn't an injurious element in it to harm or chafe the tenderest skin.

If your dealer hasn't got it send us his name and address and we will send you a trial size cake free.

3. What improvement is claimed to be effected by the invention?
4. How is the improvement effected?
5. What patents, if any, have been issued for this invention?
6. What citations, if any, were made in this regard by the Patent Office before allowance of patent claims?
7. Is the invention now in actual use?
8. If so, since when?
9. Where may it be seen in operation?
10. Are you prepared to submit drawings of the apparatus or device?
11. Are you prepared to submit a model of the apparatus or device?
12. If the invention is a composition of matter, are you prepared to submit specimens of the ingredients and of the compound sufficient for the purpose of experiments?
13. If the invention is a chemical process, are you prepared to give a demonstration of the same?

It is required also that the applicant submit two copies of each of the United States patents issued to him, with the answers to the above. He should send in also whatever additional information may be called for by the nature of the discovery.

The application is first referred to a sub-committee on new subjects and preliminary examination, which recommends to the general committee acceptance or rejection. This sub-committee and the general body hold formal meetings once a month, but this does not begin to indicate the vast amount of free time devoted to inventions. Regular meetings are held mainly for the purpose of coördinating the reports of investigation and experiment on the matters under consideration. When this sub-committee recommends an investigation a special subcommittee is appointed to conduct it. As a rule the sixty members of the general committee comprise experts in every line of mechanical and scientific work, but the institute has provided that wherever necessary the Science and Arts Committee may include in the investigating body "a minority of other persons whose expert services are desired in the examination."

There are other regulations for the protection not only of the institute, but of the applicant as well. One provides that "no person shall be a member of a subcommittee on investigation who is interested in the issue." Other regulations containing information that may be of value to inventors who may plan to make application to the institute are as follows:

"Sub-committees shall whenever possible make direct examination and tests of the subject under investigation, and shall not accept tests, data, or information furnished by others without first satisfying themselves as to the accuracy thereof. They shall in no case recommend an award solely on the basis of tests, data or other information furnished by parties in any way interested in the subject of the award. Sub-committee must ascertain that articles, processes, products, etc., examined are genuine samples of the subject under investigation."

The sub-committee may recommend award of the Cresson medal, the Howard N. Potts medal, the Edward Longstreth Medal of Merit, or the Certificate of Merit. These are awarded for the following reasons:

The Elliott Cresson Medal: For discovery or original research, adding to the sum of human knowledge, irrespective of commercial value; leading and practical utilizations of discovery; and invention, methods or products embodying substantial elements of leadership in their respective classes, or unusual skill or perfection in workmanship.

The Howard N. Potts Medal: For distinguished work in science or the arts; important developments of previous basic discoveries; inventions or products of superior excellence or utilizing important principles; and for papers of especial merit that have been presented to the institute and published in its journal.

Edward Longstreth Medal of Merit (with a money premium when the accumulated interest of the fund permits): For meritorious work in science or the arts, including papers relating to such subjects originally read before the institute, and papers presented to the institute and published in its journal.

Certificate of Merit: To persons adjudged worthy thereof for their inventions, discoveries or productions.

The Committee on New Subjects and Preliminary Examination for this year consists of seven members of the general committee and is typical of the wide variety of interests represented in the membership of the Franklin Institute. The chairman is Dr. H. J. M. Creighton, assistant professor of chmeistry at Swarthmore College. Other members are Charles E. Bonine, practicing electrical engineer; Nathan Hayward, president of the American Dredging Company and a consultant for the Bell Telephone Company; Lionel F. Levy, manufacturer of fine screens for half-tones; Charles W. Masland, manufacturer of carpets and textile expert; M. M. Price, chief engineer for the Babcock and Wilcox Company, and James S. Rogers, an attorney.

There is hardly a member of the general committee whose record does not require considerable space in "Who's Who," and all are known in scientific or technical lines. One man, Hugo Bilgram, has been a member of this committee continuously since 1873. His hobby is mathematics, and he is nationally known as a manufacturer of gear teeth and precision machinery. A few others of note are Dr. James Barnes, professor of physics at Bryn Mawr College; W. C. L. Eglin, vice-president and chief engineer of the Philadelphia Electric Company; Dr. A. W. Goodspeed, professor of physics at the University of Pennsylvania, and Dr. Gaetano Lanza, emeritus professor of mechanical engineering at the Massachusetts Institute of Technology and now consultant to the Baldwin Locomotive Works.

Direct service is given by the institute to young men of a mechanical or scientific turn of mind through its classes in mechanical drawing, architectural drawing and design, freehand drawing and water color, shop arithmetic and algebra, plane geometry and trigonometry, applied mechanics and machine design, and theoretical and practical naval architecture.

## What About Our Wheat Production?

CONSIDER the physical character of alfalfa! It is hardy and most prolific. Given deep and mellow seed beds, and the proper amount of moisture, it will produce most prodigiously. It is one of those legumes which are capable of absorbing the free nitrogen of the surrounding atmosphere, and of depositing this important chemical in its roots and branches, the former being provided with multitudes of nodules for the storing of the nitrogen. Mechanically no known plant is better adapted to the tilth and fertility of the soil in which it takes root.

Alfalfa is not only a profuse but a deep rooter. In certain instances alfalfa roots have been known to penetrate the earth to a depth of thirteen feet or more. It is a bushy plant, with vigorous, fibrous stalks and branches and a luxuriant leafage. So when it comes to plowing in the last growth of a season we have, from above ground, a mass of plant growth, and from below a deep and intricate network of rootage. All of this vegetable matter is turned under by the plow, decays and imparts to the soil that vital element known as humus, or vegetable matter in process of decomposition.

And we find the root material nicely distributed for the purposes of fertilization; and the soil, after the decay of this mass of rootage, honey-combed by myriad little root tunnels, a condition that renders the soil mellow and most susceptible to proper aeration, and absorption of moisture.

W. L. Douglas
THE SHOE THAT HOLDS ITS SHAPE
$7.00 $8.00 $9.00 & $10.00 SHOES
FOR MEN AND WOMEN
YOU CAN SAVE MONEY BY WEARING W. L. DOUGLAS SHOES

The best known shoes in the world. They are sold in 107 W. L. Douglas stores, direct from the factory to you at only one profit, which guarantees to you the best shoes that can be produced, at the lowest possible cost. W. L. Douglas name and the retail price are stamped on the bottom of all shoes before they leave the factory, which is your protection against unreasonable profits.

W. L. Douglas $9.00 and $10.00 shoes are absolutely the best shoe values for the money in this country. They are made of the best and finest leathers that money can buy. They combine quality, style, workmanship and wearing qualities equal to other makes selling at higher prices. They are the leaders in the fashion centers of America. The stamped price is W. L. Douglas personal guarantee that the shoes are always worth the price paid for them. The prices are the same everywhere; they cost no more in San Francisco than they do in New York.

W. L. Douglas shoes are made by the highest paid, skilled shoemakers, under the direction and supervision of experienced men, all working with an honest determination to make the best shoes for the price that money can buy.

W. L. Douglas shoes are for sale by over 9000 shoe dealers besides our own stores. If your local dealer cannot supply you, take no other make. Order direct from factory. Send for booklet telling how to order shoes by mail, postage free.

CAUTION.—Insist upon having W.L.Douglas shoes. The name and price is plainly stamped on the sole. Be careful to see that it has not been changed or mutilated.

# "Am I Going to be Huck Finn?"

Artists have tried and failed to put Huck Finn on canvas.

So we turned to the photographer. "I know the very lad," he said, and called him in.

His freckled face was one ecstatic grin.

"Gee, am I really going to be Huck Finn?" he gasped. "There's nothing I've ever wanted to be so much as Huck! Ain't this great!"

Then the camera clicked and here he is.

Did you ever want to be Huck Finn? Be him in your mind. Read

# MARK TWAIN

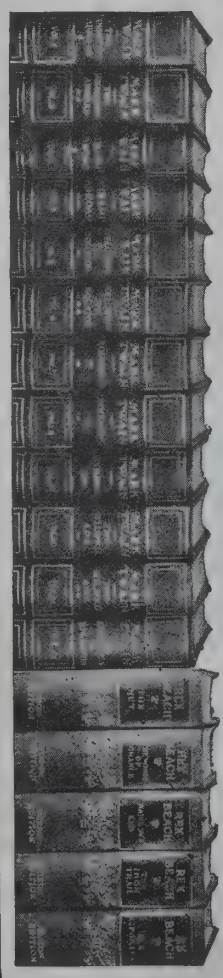
## *12 Volumes at a Low Price*

**Humor — Biography — History — Travel — Boys' Stories — Essays — Novels**

What has America contributed to the classics of the world? The answer comes in one great, swelling chorus. From the Golden Gate to China's Wall—from Alaska to the Australian Bush—from colorful harbor of Singapore—from the Argentine to the English Channel—from the Hebrides to the Mediterranean—the answer rings firm and clear—MARK TWAIN.

# FREE — REX BEACH

## *5 Volumes*



Rex Beach is the most popular writer of thrilling stories living today. He is the man who knows, as no other, the big outdoors that is the Klondike.

Plenty of humor—plenty of scrapping—big, raw-boned men who can whip their weight in wildcats—the women these men fight for and die for—all these you will find in Rex Beach's vivid, human novels.

## Only a Few Sets FREE

Rex Beach now costs you $2.00 for each volume in the book store. But we have made a small special edition. As long as this small special edition lasts, you can have 5 volumes—$10.00 worth of books—absolutely free.

Rex Beach has sacrificed much of his royalty so that we can do this on one edition.

If you are prompt you can get your set free. If you are too late we will return the coupon—But don't wait.

Send coupon for both sets for examination.

Send no money—Just the coupon.

Send it at once.

HARPER & BROTHERS
Est. 1817

Send me, all charges prepaid, a set of Mark Twain in 12 volumes, illustrated, bound in handsome green cloth, stamped in gold, and Rex Beach in 5 volumes, bound in red cloth, free. If not satisfied, I will return them at your expense, otherwise I will send you $1.50 within 5 days and $2.00 a month for 14 months.

Name .....
Address .....
Occupation .....

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.

(14352) L. M. A. asks how to separate gold and platinum. A. Usually where there is gold and platinum there is also silver in the alloy. To separate them, be they in filings or pieces, reduce them like gold with aqua regia, in a porcelain dish; cover with a glass funnel; set in a chimney or where the fumes can escape on hot sand, until the metal is all dissolved. Let it remain in the warm sand bath until the liquid has evaporated to the consistency of syrup, and then let cool. Pour on enough muriatic acid to well cover the syrupy mass, cover again with the funnel, and let evaporate on the sand bath again till a syrupy mass results. To every gram of metal five grams of water are added to the mass, well mixed and boiled for half an hour. Let it get cold, then filter through a close filter paper and a glass funnel, and the particles remaining in the filter paper are silver. The silver on the filter paper can be melted in the usual way. The above filtered solution is now treated for platinum. In a pint of boiling water put 200 grams of powdered sal ammoniac and let dissolve; then mix this with above solution, stirring well with a glass rod. Let stand for two or three hours to settle. The platinum gathers in an orange-like mass at the bottom which is the chloride. Filter off the top carefully without disturbing the yellow very much. The yellow mass is mixed with about 300 grams of water, well stirred. Keep on stirring and filter through the already used filter. Let drip out well and the precipitate on the filter is platinum. Let this dry for 24 hours, place in a crucible, pressing the filter paper in well so it will serve as a cover. Heat gradually until no more smoke rises and a white-red heat is obtained. Let cool, then melt again and run into an ingot or button.

(14353) R. F. N. asks how to clean tarnished gold after hard soldering. A. Before attempting to solder gold, paint over with a paste made by mixing yellow ochre ground up with water and a small quantity of borax. This paint will somewhat protect the surface from oxidation. After soldering, the gold should be placed in a pickle composed of nine parts water and sulphuric acid 1½ parts. It is best to throw the gold in the pickle while still hot from the soldering. Very often the soldered and pickled gold will show whitish in streaks, caused by the silver in the alloy. If so, dip for moment in a hot pickle solution of sulphuric acid and saltpeter, then dip in cold water, wash clean and proceed to polish, first with rotten stone and oil. Wash again and finish polishing with rouge.

(14354) H. W. J. asks: I am a constant reader of your magazine and would greatly appreciate information through your columns concerning the behavior of lines of magnetic force, preferably lines around a permanent magnet. The specific information is to know if it is possible to "insulate" to any extent a permanent magnet so that the lines of force will not attract steel or iron. In other words is there any substance, solid, liquid or gas which can be placed between a magnet and its armature or attracted object so that that attraction is no longer felt by the object or witnessed by an observer? If there is no such substance, why not? or is it an impossible thing and oblige. A. Lines of magnetic force cannot be confined in a space as the electric current can be by insulation. The only way in which they can be prevented from entering a space is by furnishing them with an easier path around that space. Iron furnishes such a path, since its permeability is greater than air or any other substance. A magnet is protected, insulated, if placed in a box of rather thick iron, perhaps a half inch plate.

(14355) R. M. S. asks: Please be so kind as to give us information in regard to light and heat from the sun direct. It is taught in our schools that we receive light and heat directly from the sun, as we do from a bonfire, as we stand near it at night. On the other hand some scientists say not so. That in all those 95 millions of miles it is intensely cold and dark and therefore impossible for light or heat to pass through. So in our schools and colleges are they teaching a lie? If you will kindly answer this it will be greatly appreciated by a number of us inquisitive ones who wish to know. A. The rays of the sun as they pass through space are neither haet nor light. They are capable of becoming heat if they strike anything which can be heated, your hand, for instance, or they will become light if they strike an eye which can transform them into light. The heat from a bonfire heats the air because the air can receive it, but it will not heat a vacuum where there is no air. Space, empty space, we often call it, but it is not quite correct to call it empty, is not heated by the rays of the sun. The air itself at high altitudes is not heated very much by the sun's rays as they come down through it as is seen by those who find it extremely cold upon going up in airplanes or balloons. The powerful rays of the sun lose very little of their energy in passing through space because there is very little there to intercept them. They lose some more in our upper air but still have great power left which they give the earth at its surface, enough to produce the growth and life which we see.

(14356) R. L. W. asks how to refine commercial gold. A. If one desires to obtain pure gold from gold of inferior qualities the scraps should be treated in the following manner: To one ounce of mixed qualities of gold add two ounces of fine silver. Place the material in a plumbago crucible and melt in a good furnace, a little powdered charcoal being added to protect the fusing mass from the action of the air, which would otherwise cause a scum to appear on the surface. When the mixture is thoroughly melted it must be formed into a deep vessel of cold water kept well stirred in a circular direction during the operation; this will cause the fused alloy to break up into small fragments; or the fused alloy may be poured into a hot ingot mold and afterward rolled down into thin sheet metal and cut up into pieces sufficiently small to enter the mouth of the dissolving flask. The object in doing this is to present as large a surface as possible to the action of the acid which is employed to dissolve the metal. The small particles of metal are carefully collected together and placed in a glass dissolving flask, and to each ounce of the alloy two ounces of pure nitric acid and two ounces of water are added. The flask is then placed on a sand-bath and gentle heat applied until all the metals—with the exception of the gold—are dissolved into the liquid; the gold remains undissolved at the bottom of the flask, in a finely divided form of pure metallic gold. It will thus be seen that the acid mixture dissolves the silver and copper but not the gold. The brown powder of metallic gold is then washed well with either hot or cold water and the washing added to the first solution which was poured away from the gold in the flask. The gold is next dried and melted in a clay crucible under a small quantity of dried common salt, and should then be quite free from base alloy. If the gold is required for making a gilding solution, it may be taken in the powdery state, direct from the washing operation, and dissolved in aqua regia, and subsequently converted into chloride of gold. It may be advisable to obtain absolutely pure gold to add a little fresh acid to the gold powder before removing it from the flask, to make sure that all the silver and copper have been removed. Heat must be applied as before to cause full chemical action. The silver and copper will be in the fluid poured from the dissolving flask in the form of nitrate of silver and nitrate of copper, and should be preserved with the view of recovering the silver.

(14357) C. F. D. asks: As farm lighting plants generally are of 32 volt potential am I right in concluding that that is as high as permissible? What is the highest voltage direct current that is considered safe for children and other people to handle? A. Farm lighting plants are generally run so that the dynamo is not run all the time, but charges a storage battery and this supplies the lamps in the evening when it is not convenient to run the dynamo, if run by water, or impossible to run it, when it is calm, if run by a windmill. The cost of a storage battery is so large that the voltage of the lamps and other machines is kept as low as can be, so that the number of cells in the battery may be as small as can be. The usual voltage of an incandescent lighting circuit is 115, and this is quite safe. It might be that a peculiarly susceptible person would be injured by a shock from it, but ordinary people only feel it as a needle or pin prick. 300 to 500 is the limit of low voltages. Above 500 the shock is severe.

. . . and at New York's
Home of Grand Opera

*A fact:* All during last season at the Metropolitan Opera House—whose every audience is typical of the best in New York society—the sales of Fatima exceeded those of any other cigarette.

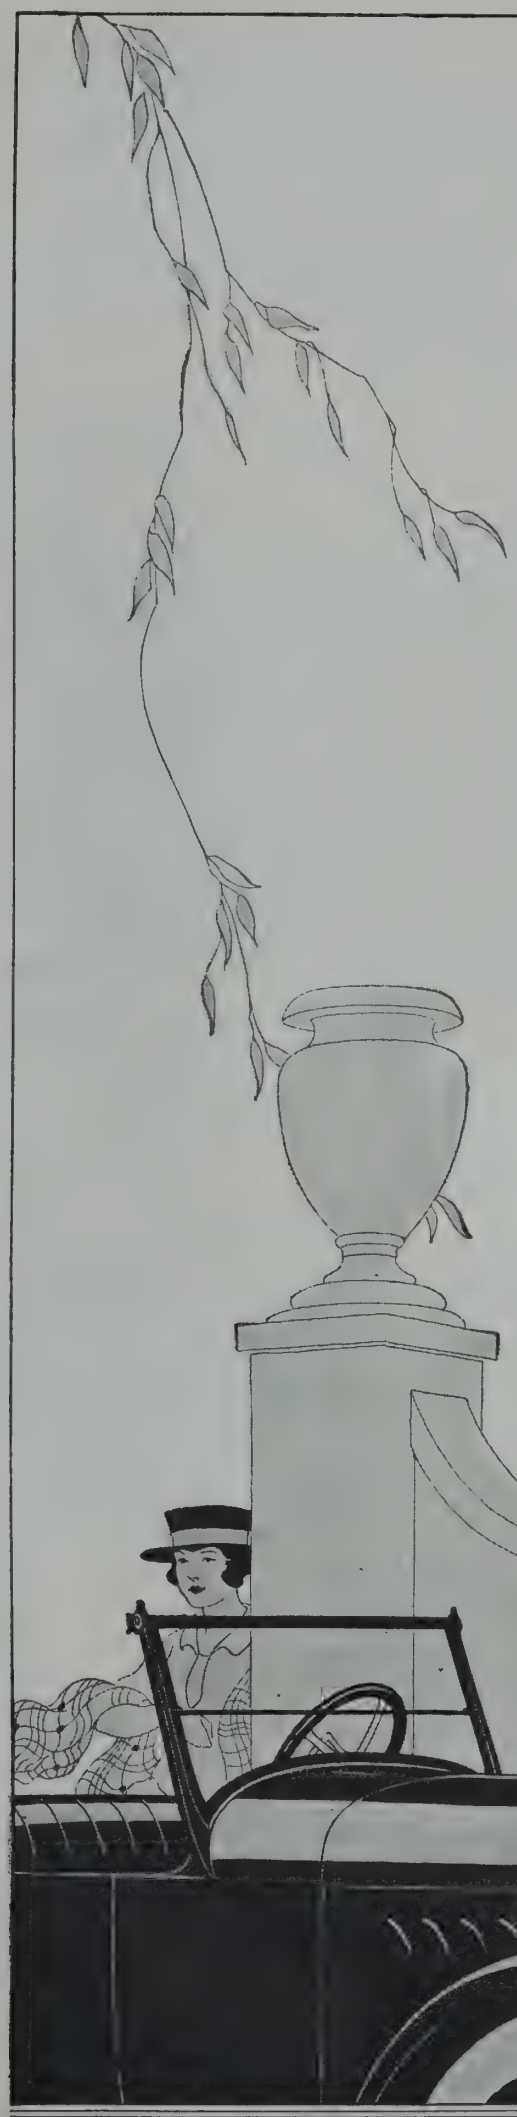
Liggett & Myers Tobacco Co.

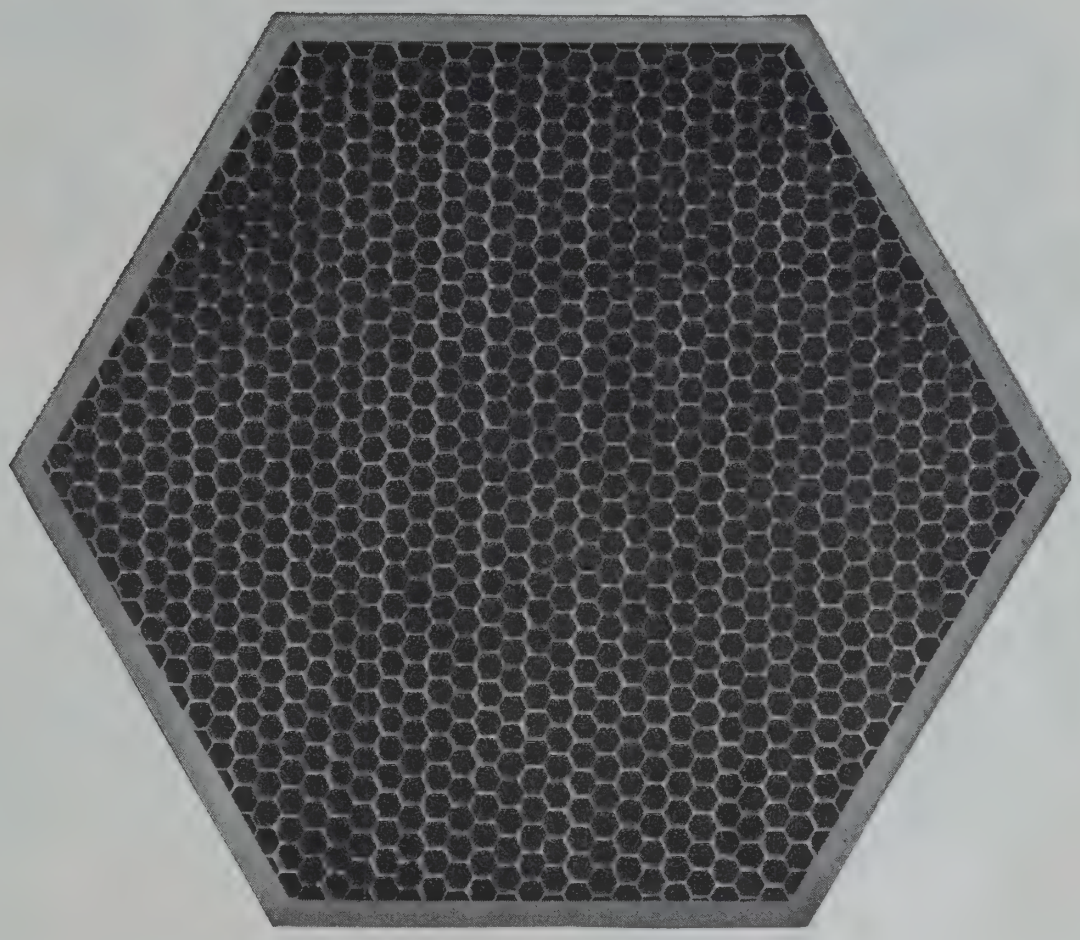
# FATIMA
## CIGARETTES

*—more proof of "just enough Turkish"*

At most exclusive clubs and fine hotels the leading seller is Fatima.

Fatima's famous "just enough Turkish" blend lacks the oily heaviness of expensive, all-Turkish cigarettes, but has a smoothness and richness not found in any other Turkish Blend cigarette.





THE kinship of quality, which leads one fine character to seek another equally fine, naturally leads manufacturers to equip fine motor cars with Harrison Radiators.

Their distinctive beauty and their ability to render efficient engine cooling service at all seasons, make Harrison Radiators the logical choice.

The Harrison-equipped Lexington is an example of this kinship of quality.

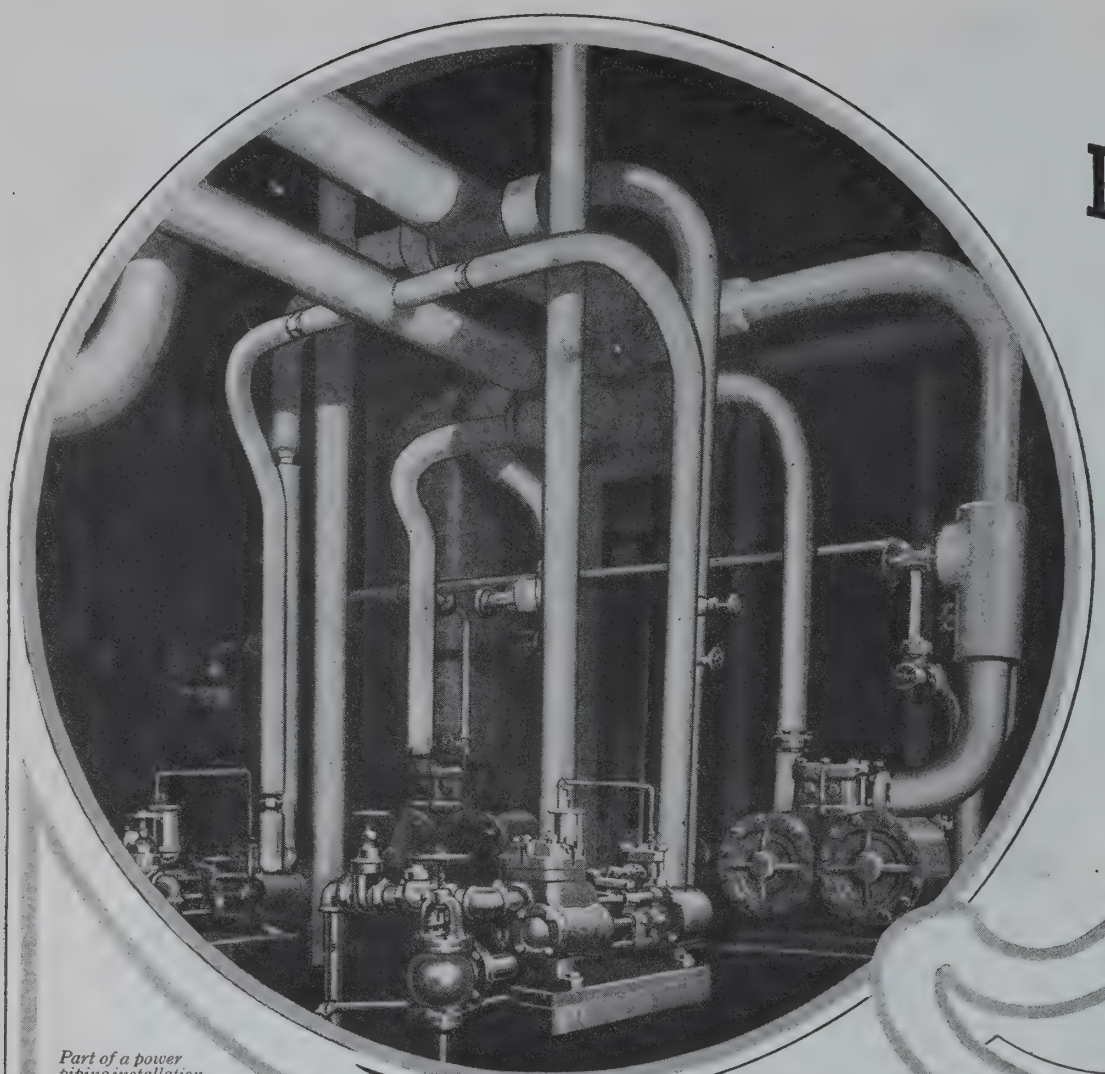
# INDUSTRIAL PIPING EQUIPMENTS



*Part of a power piping installation at the Rhode Island Co., Providence, R. I.*

SCIENCE AND SERVICE

ASK YOUR CONSULTING ENGINEER

## Are Shut-downs Inevitable?

A BREAK-DOWN in piping equipment often causes a shut-down, a shut-down entails dissatisfaction of labor, delayed orders and disorganization. The breakdown may involve a process, or a department, or the whole plant. While you read this statement, repairs are under way in a thousand industrial piping systems, while the managements and labor wait for a chance to resume production.

Inevitable? Not if we accept the judgment of consulting Engineers and experienced plant Superintendents. They tell you almost to a man that this waste is due to poor design, faulty materials, or poor installation. It has been said on the best of authority that sixty per cent. of the steam power plants in New England could be modernized at a profit to owners—a handsome profit on investment. Generally the inefficient equipments are the older ones and the fault is due to the fewness of *experienced* organizations that were doing such work 20 or more years ago.

The Grinnell organization had at that period a half century of experience in industrial piping, with factories, engineers and construction forces doing work in many States, North and South. Such experience, now covering 70 years, cannot be recorded on the printed page, but it is readily passed along among our designers, superintendents and foremen, year after year, decade after decade.

Concerns requiring industrial piping service should find in our experience, rather than in our magnitude, the reason for considering us today.

1. The train and its passengers. There are usually five cars and the passengers are divided evenly on either side. 2. The bizarre monorail locomotive of the railroad. 3. A road crossing, using a lift bridge to cross the railroad track. 4. A farmer using the monorail track as a gate to his front yard. Between train times the gate is left open for the farmer's convenience.

**Ireland's monorail steam road which is decidedly out of the ordinary**

Copyright, E. M. Newman

## A Curious Little Monorail Road in Ireland

THE odd little locomotive, cars, and track, of which we show several views, are to be found in a picturesque part of Ireland beloved by the tourist, for it runs from Killarney to Bally Bunion. In spite of its novelty, at least to American eyes, it is by no means new, for it has been serving the district through which it runs for lo, these many years.

During the closing years of the nineteenth and the opening of the twentieth centuries, railroads running on a single track had quite a vogue, particularly among people of an inventive turn of mind. Steel rails cost money, and so do the broad track and expensive ties on which the rail is laid. How natural, then, to seek an escape from the high cost of railroad construction by cutting the width of the tracks in half, throwing out one rail altogether, and reducing the number of wheels beneath the locomotives and cars by one-half.

The attempt to build a satisfactory monorail system produced a great variety of designs, many of which were illustrated from time to time in the SCIENTIFIC AMERICAN. There was the overhead monorail, as used in Germany, in which the cars are suspended by means of what is actually a massive hook from a pair of little trolleys which engaged the single overhead carrying rail. Another system which was tried out on a short length of trolley line running to City Island, New York, had a single track laid upon the roadbed with a steadying overhead rail, carried on standards at the side of the track, which was placed above the cars and was engaged by a pair of small wheels carried in a stout rigid rig extending from the roof of the car.

The Bally Bunion monorail system is practicable, but we believe has never been extended beyond its present length and has never shown any advantages over the standard system of railroad track construction which would warrant the system being brought into extensive use. The carrying rail is mounted at the apex of a series of A-frames which are bolted down to short wooden ties. At about one-third of the height of the A-frame is mounted a pair of steadying rails which engage rollers on the cars and serve to keep the rolling stock in a vertical position.

The latter is built in two sections; and this is carried so far that steam is generated in two diminutive little boilers which are mounted one on each side of the track. The cars also are built in two halves, and, like the locomotives, they are carried by plate-steel frames in which the main carrying wheels for transferring the load to the track are mounted. The cars are of the well-known British and continental pattern, with separate compartments and a side door to each compartment. Very curious is the simplicity of the track arrangements of this railroad. Take note of the road crossing, in which the roadbed consists of two hinged, counter-weighted leaves, which are raised and lowered by means of chain and pulley on each side of the track. A decided curiosity is our picture of an Irish cottage, where the gate to the yard consists of a section of the track which is so mounted on a vertical standard at one end, that it can be swung open for a wagon and shut for a train.

## Living Bean Poles

AS the nation's lumber supply has dwindled and market prices for wood risen markedly, substitutes for wood have been originated. The paper boxes now in such extensive use as shipping packages are some such. The garden is a queer place to look for substitutes for wood, but you can find them there.

A gardener in an eastern State remarked the other day that he believed bean-poles would cease to be common sights in city backyard gardens because of their cost and the difficulty of obtaining them. He said that a substitute for them had been found—the Giant Russian sunflower. Many small gardeners last season used sunflowers for poles. They planted two or three seeds with each hill of climbing beans, and thinned to leave one sunflower plant to each hill.

Up this live "pole" the beans twined and ascended. The gardener kept all leaves off the sunflower except several at the very top. They made excellent poles, yielded a crop of their own, and were cheap. Low cost, and the convenience with which they are provided, are big advantages of the sunflower bean-pole.

Of course, the sunflower isn't the first make-shift bean-pole. Throughout those farming regions of America where wood is scarce, climbing beans for decades have been planted almost wholly in the corn. There are Western farmers who don't know what you mean when you speak of "pole" beans. They call them "cornstalk" beans, because of the universal use of the makeshift pole. A cornfield is not an ideal place for beans, however, because of the degree of shade.

## Problem of the "Leviathan"

WITH the three largest transatlantic liners in the world for sale and no bidders, the question presents itself as to whether dimensions, speed and luxurious appointments have not been pushed too far, even to the point of *reductio ad absurdum.*

The public is more or less familiar with the case of the "Leviathan," formerly the "Vaterland" of the Hamburg-American Line, which made her maiden trip to this port a few weeks before the war, and with the exception of a term of service as a transport, has been tied up continuously at her dock at Hoboken for the past six years. Subsequent to the armistice, the Government offered this magnificent liner for sale, and a bid of $3,000,000 was put in with a proviso that the Government should make a loan, at a low rate of interest, of $6,000,000 to enable the company to put her in condition. The bid was rejected and the ship still lies at her pier with a caretaking crew aboard, who with grease, oil can and paint pot, are doing their best to prevent deterioration.

The original cost of this 54,000-ton ship, although she was built at pre-war prices under the economical system of a first-class German yard, must have been from $8,000,000 to $10,000,000. To reproduce the ship today would cost twice that sum, and the cost might well run up to $25,000,000. True it is that the cost of reconditioning the ship and turning her into an oil burner would be heavy. On the other hand passenger rates on a ship of her class are proportionately high, if not higher, and once in service she should attract the cream of American travel to herself—provided the cuisine and general service were begun and maintained at the high level reached by her competitors. Failing that she would be an unutterable failure.

We are rather inclined to think that the reluctance among our shipping men to take charge of the "Leviathan," either by outright purchase or by charter, is due in some measure to a conscious lack of experience in what might aptly be called the floating hotel business. On the technical side they have no anxiety whatever, for our engineer force got greater speed out of the "Leviathan" when she was in transport service than she had ever shown in German hands, and as navigators our merchant officers are second to none. But when it comes to receiving some three thousand people aboard ship, and feeding and housing them with the delicacies and comforts of public hotel or private home, the problem assumes stupendous proportions and calls for long experience and very expert skill. It is one thing to run a 5,000-ton passenger ship to the West Indies but quite another thing to run a 54,000-ton "Leviathan" to Europe.

Another of the big ships that is on the list for sale is the "Bismarck," sister to the "Leviathan" and built at the same yard on the same building ways. Work was carried on in a desultory way upon her during the war, and Germany has undertaken to complete the ship and place her at the disposal of the Allies. Structurally she is complete, we believe, the unfinished work consisting of the fitting and furnishing of the passenger accommodations. The Germans are urging that she be broken up and the material be used in the construction of ships of a more usable size. So far as ownership is concerned, she has passed out of their hands, but the suggestion shows that her builders are disposed to look upon this huge passenger ship as something of a white elephant. This much is certain, that among the many rumors regarding the "Bismarck" there has never been so much as a hint of a prospective purchaser.

The third ship, "Imperator" of 52,000 tons, was apportioned to Great Britain as part of the compensation for the destruction of 9,000,000 tons of her shipping during the war. She is being operated by the Cunard Company pending her sale; but apparently no satisfactory bids have been received, for she is still Government property and is likely to remain so for some months to come.

## Why Not the Torpedo Motor Boat Carrier?

IN the contest last summer for the Harmsworth Cup the race was won by a little 26-foot motor boat which is credited with an official speed of 70 miles an hour. It detracts nothing from the credit of the victory to say that "Miss America" consisted of a pair of Liberty engines with a boat built around them. She showed what the gasoline motor was capable of doing under extreme conditions of maximum power of engine and minimum size and weight of boat.

To the serious naval constructor, who at no time in the progress of his art has been hedged about with so many and so difficult problems as today, the mere fact that any kind of a sea craft has made 70 miles an hour should be a matter of great significance. He knows full well that, starting with a basis of two Liberty motors, or 800 horse-power, which is what "Miss America" carried, it would be possible to build a torpedo-carrying motor boat whose offensive power could be increased in proportion as speed was sacrificed. To put it more concretely, he could make a guess offhand that a modified motor boat of the "Miss America" type, larger, stronger and more seaworthy, could be built that would carry a 21-inch torpedo at a speed of 40 knots. "Miss America" was built for fair weather and smooth water, and it is well understood that the phenomenal speed of these little craft falls in proportion as the seas run high. Nevertheless it is quite possible, by increasing the size and modifying the model, to produce high-speed craft which will hold their speed under conditions in which the out-and-out hydroplane of the "Miss America" type would be helpless.

Rear-Admiral Taylor, Chief Constructor, in his recent masterly summing up of the naval lessons of the war before the Franklin Institute, commented favorably upon the work done by Allied motor torpedo boats during the war. "The little boats," he said, "performed splendid service off the Belgian coast," referring, no doubt, to the British 40-knotters, which, on their very first cruise sank a German destroyer. He stated also that "the most spectacular and at the same time most valuable service performed by boats of this type was the daring penetration by the Italians into a fortified Austrian harbor, where they sank a battleship lying at anchor. Later, in operations against the Bolshevists, a small British flotilla penetrated to the inner harbor of Kronstadt, where they succeeded in sinking two battleships and two other large vessels."

These performances seem the more remarkable when we remember that they were accomplished by experimental vessels, the first of their type to be built. Subsequent improvements, as worked out in this country, are in the direction of greater size and seaworthiness, coupled with a wider range of action, better accommodations for the crew, and ability to carry the largest torpedoes.

The point is made by the naval constructor that the objection to such craft is that they are too small to keep the sea with the main fleet. It is undeniable, on the other hand that, were it possible to take two or three flotillas of 40-knot, torpedo-carrying motor craft into such an action as that at Jutland, they would inevitably exercise a controlling influence on the tactics of the battle, and might well prove to be its deciding factor; for we must remember that there was a calm sea at Jutland throughout the whole of the day and night engagements.

But how are motor boat flotillas to reach the scene of a battleship engagement on the high seas? They have neither the cruising radius nor the sea-going qualities to enable them to cruise with the fleet. So, if they are to get to Jutland, they must be carried there. In this respect the problem is parallel to that of the airplane which, it was known, would be a formidable weapon could it be present in numbers at a naval engagement. In the case of the airplane the problem was met by designing special airplane carriers, and in the case of the torpedo motor boat it can be solved in the same way by providing motor boat carriers. These would be unarmored cruisers about 800 feet in length and of 35-knot speed, specially built for carrying forty boats on two decks. The boats would be stowed, two abreast, throughout the full length of the ship, and electrically operated davits would be provided with gears sufficiently powerful to put the first flotilla of twenty boats in the water within a few minutes' time and a second flotilla of the same size shortly thereafter.

It is a question worthy at least of consideration, whether four such ships, taking position on the four wings of an enemy's line of battle would not constitute a more deadly threat than four battle-cruisers of the same size and speed. We do not say that they would, but we do claim that the question is worthy of the most careful consideration of our naval constructors, of our War College and of the General Board of the Navy.

## Invention or Discovery

A. H. WALKER, in his standard work on Patent Law, draws a definite line of demarcation between invention and discovery. "The statute provides that patents may be granted for four classes of things. These are arts, machines, manufactures, and compositions of matter. None of these things can be originally made known by discovery, as our continent was. They are not found but created. . . . Laws of nature, on the other hand, can never be invented by man, though they may be discovered by him."

For practical purposes of patent and copyright law this distinction may be well enough. But if we love argument, we may enunciate the proposition that invention is the discovery of a fact or facts in the realm of the mind, just as geographical exploration, for example, may lead to discoveries in the realm of objective things. This may seem far-fetched, but the proposition finds support in the words of no less an authority than Emerson. For, "Poetry was all written before time was." This is not the place to quote the great essayist at length. Those who wish to refresh their memories may do so by consulting the original. Suffice it to say, that Emerson looks upon the poet, not so much as a creator, an inventor, but rather as the interpreter, the discoverer of that which existed from all time; the man whose ear is delicately attuned to the music of the spheres; whose eye is keen to discern the great truths, "which others, knowing not, pass blindly by."

We may subscribe, broadly, to Emerson's point of view, and look upon invention as the discovery that a thing can be done in a certain way, a thought expressed in certain words; and this without endorsing the insane scheme of a certain madman, of whom we read years ago, who proposed to discover all truth by writing out all words of our language in every possible combination. Some of these combinations, he said, will form sentences revealing great and new truths, and by continuing long enough we shall eventually know all truth. The reader who is mathematically inclined may amuse himself by figuring out what the probabilities are of hitting on a new truth by this method within a week, a year or a century. We recall, too, from our school days, a mechanical device, a sort of multiplication table, for composing Latin verse without mental effort. Making all allowance for the use of Roget's Thesaurus, of rhyming dictionaries and other mechanical aids to composition, it is not, of course, by any such devices as this that the great writer, or even the lesser author, makes his "discoveries." But we may liken the writer's mind to a kaleidoscope; under the stress of intense feeling (which underlies all the best in literature), the right words come to mind spontaneously, and array themselves in rhythmic cadence, as if reflected into a well ordered pattern by the facets of his mind, like the many colored prisms in the kaleidoscope, tumbling in fortuitous disorder, yet ever complementing each other, through the mirror, into a pretty geometrical design.

## Electricity

**An Electrically Welded Ship.**—From the London *Engineering* we learn that the "Fullagar" is an entirely welded ship. The success of this ship has shown that welding is effective for all purposes in such work. It is not claimed that it is necessarily the cheapest method. The ship is one of 25,000 cu. ft. displacement.

**Radio Equipment of the "Vaterland."**—On this ship recently recommissioned, there are three complete wireless transmitters, one of which is worked in connection with a high-frequency generator, this being the first instance of the use of such a generator on board ship, according to *Wireless World*. For transmitting on waves of 600 to 1,800 meters, and for use with the high-frequency generator, an aerial 190 meters long is carried. For shorter wave lengths and for emergency transmitting two other aerials are provided, each consisting of a single wire spread between the funnels.

**For Testing Dry Batteries.**—The Bureau of Standards, Washington, D. C., has issued technologic paper No. 171, entitled "Automatic Apparatus for Intermittent Testing," which describes equipment devised to meet the needs of the bureau in making tests of dry cells and storage batteries, but is applicable to nearly any form of intermittent testing requiring the closing of electrical circuits at regular time intervals. The particular advantages of this type of apparatus for making these tests are: Elimination of rapidly moving parts, accuracy of the time intervals, and possibility of making a number of different tests simultaneously with the same apparatus.

**The Printing Telegraph** is being employed more and more for press news service. In fact, the American Telephone & Telegraph Company expects to change the press news service over to printing telegraph machines as fast as it is practicable to do so. For several years the company has used the printers for a portion of this service in New York, Boston and Chicago, and much of the company's inter-office communication between New York and Chicago is carried on by this means. The printing telegraph has now been developed so that, depending on the class of service, a transmitting speed of twenty to sixty words per minute can be obtained, and by means of synchronized machines sixteen messages, or eight in each direction, have been sent over one wire.

**A Self-Exciting Mercury-Arc Rectifier.**—A difficulty with ordinary mercury-arc rectifiers is their tendency to go out if the load drops below a certain point. There has recently appeared in Germany a new kind of "self-exciting" rectifier, which will keep going even if the load is completely shut off. The new rectifier type is of glass, quite similar to current models, but is provided with two auxiliary anodes fed from a special winding on the input compensator, according to *Elektrotechnische Zeitschrift*. The winding has a midpoint tap which is connected to the cathode, and in the auxiliary-anode connections are inserted two resisters, so that the auxiliary system forms, as it were, a small rectifier within the power rectifier. This auxiliary rectifier system takes about 100 watts, is started in the ordinary way and is always kept running. It will then automatically excite the power arcs so that the main rectifier starts as soon as the direct-current output circuit is closed, and the rectified current thus is perfectly stable down to very small current strength.

**Something New in Arc Lamps.**—About two years ago we had something to say regarding a novel form of enclosed arc employing tungsten electrodes and enclosed in a high vacuum, developed in England. At that time the inference was that the lamp was of a purely experimental nature, but we learn of late that this arc lamp is a commercial success. Briefly, the lamp resembles a round incandescent lamp so far as exterior design is concerned. Instead of the usual filament, however, the lamp contains a small ball of tungsten, a horizontal tungsten rod, and a small tungsten coil right over the tungsten ball. To start the arc the vacuum must first be bridged, since the electrodes are fixed. This is accomplished by passing a current through the tungsten filament which becomes incandescent and heats the surrounding vacuum. Then the current is switched over to the gap between the horizontal tungsten rod and the tungsten ball. The heated vacuum, no longer being an insulator, carries over the 110-volt current and the tungsten ball is heated to incandescence by the arc. The result is an extremely concentrated source of high candle power, suitable for numerous purposes. At present M. Belin, the inventor of the system for transmitting photographs over telegraph and telephone lines, is using such a lamp for the source of light in his receiving set. The details of M. Belin's apparatus appeared in our November 6th issue.

## Science

**Medical Congress in Batavia.**—The Fourth Congress of the Far Eastern Association of Tropical Medicine will be held at Batavia, Java, in August, 1921, under the patronage of the governor general of the Dutch East Indies. The third congress was held at Saigon, Indo-China, in 1913.

**Februaries with no Full Moon.**—An English writer, Mr. S. H. Gaythorpe, has computed the number of years in the 19th to 24th centuries, inclusive, in which the moon does not become full in February. During the 19th century this occurred in 1809, 1847, 1866 and 1885. In the present century there are only two cases; viz., 1915 and 1961. In the next four centuries there will be 14 cases. "By a singular coincidence," he writes, "this happens to be of the same degree of frequency as the occurrence of five Sundays in February, though the two events are quite unrelated, the latter happening regularly thirteen times in four centuries."

**Hay-fever Resorts.**—In Public Health Reports for September 24, 1920, Dr. William Scheppegrell publishes statistics showing the beginning and ending of the spring and autumn hay-fever seasons in each State of the Union; the plants chiefly responsible, in each State; and a list of "hay-fever resorts" for all States where such places are known. These resorts are places that are free from hay-fever pollens, and where the hay-fever patient can find relief from the disease. As the pollen of most hay-fever plants is very buoyant and will traverse 5 or 6 miles when the winds are favorable very few places in the country are absolutely free from this troublesome disease.

**A Remarkable Case of Overpopulation** is that of the Island of Bukara, in Lake Victoria Nyanza, described by H. L. Duke in the *Cornhill Magazine*. This island, with an area of 36 square miles, much of which is bare granite, though isolated from the rest of the world, supports a population of 19,000. The small garden plots are carefully marked off and rights of ownership are rigidly observed. Trees are valued more than the land on which they grow. In some cases one man owns the trees and another the ground. A man must not steal his neighbor's leaves, sticks and rubbish. A father may even divide a tree among his children, allotting certain branches to each.

**Guatemalan Reconstruction.**—A very definite program has been prepared in Guatemala City for the reconstruction of the public buildings destroyed in the earthquake of December and January, 1918-19. Present plans call for a large amount of armored concrete construction material, of approximately 20,000 barrels of cement, with a proportionate amount of structural iron for reinforcing, and of tongue and groove lumber for flooring. In addition to the plans for the housing of the Government offices the construction of roads and highways is contemplated; also the reconstruction and increase of the water supply of the city. It is reported that an electric tramway system is contemplated, with an interurban line to Antigua, some 25 miles distant.

**The American Meteorological Society,** organized in December, 1919, has already attained a membership of nearly 1,000, a good evidence of the interest now taken in the study of the weather and the atmosphere by people in various walks of life throughout the country. Professional meteorologists constitute a small minority of the membership, which includes representatives of all professions concerned in any way with atmospheric phenomena, such as aeronauts, mariners, hydrologists, engineers, medical men, etc., besides the general public. A branch of the society is being organized in Brazil by the director of the Brazilian meteorological service, and a Pacific division will probably be organized next summer. The society publishes a monthly *Bulletin*, received by all members, who pay a membership fee of one dollar per annum. The secretary of the society is Dr. C. F. Brooks, U. S. Weather Bureau, Washington, D. C.

**Remedies for Poison Ivy.**—The *American Botanist* records that Mr. W. L. McAtee of the U. S. Department of Agriculture has collected a list of 244 alleged cures for "ivy" poisoning. Among the vegetable substances recommended to be taken internally are extracts or infusions of sweet fern, snakeroot, pasque flower, aconite, spice bush, coffee, poison sumach (!), pipsissewa, yellow jasmine, belladonna, and bryony. It is pointed out that "poison ivy probably has a reputation for harmfulness all out of proportion to its abilities; a few people are rather severely poisoned by it, but the majority seem to be immune or nearly so." We should like to add that a great deal of supposed "ivy" poisoning may be due to other plants, since there are scores of plants that are capable of causing more or less severe dermatitis in susceptible people. Copious information on this subject was published in 1887 by Dr. J. C. White in his book "Dermatitis Venenata."

## Automobile

**Cost of Trucking.**—An Akron manufacturer running his own motor trucks between that city and Cleveland has analyzed the cost and time features of three competing methods of transportation. Motor trucks cost 36½ cents a hundred pounds, railroad freight, 80 7/10 cents a hundred; railroad express, $1.044 a hundred; and electric trolley express, 87 4/10 cents a hundred. Motor trucks costs include all direct and indirect charges. The average time for motor truck delivery is 4 hours and 9 minutes—for the other three methods, 12 to 48 hours.

**Sliding Gearset Trouble.**—In some transmissions of the sliding gear type the high speed or direct drive is obtained by the sliding gear, which provides the intermediate speed having a suitable extension from its face designed to mesh with an internal gear, and thus form a positive driving clutch to couple the gearset main shaft portions together. When the teeth on the male clutch member become worn considerable trouble will be experienced in securing positive engagement, and if the wear is such that the width of the teeth is materially reduced a new member will be needed. If the teeth are not worn, but are only turned over at the edges, they may be dressed to proper contour by using a very small, high speed emery wheel on the end of a flexible shaft or by removing the offending member and grinding it in any suitable machine.

**Commercial Motor Truck Exports Reflect Healthy Market Condition.**—Exports of commercial motor trucks from the United States for the months of October, November and December of 1919, and for January and February, 1920, are represented by the following figures taken from the reports of the Bureau of Foreign and Domestic Commerce:

| Month | No. | Value |
|---|---|---|
| October | 1,301 | 2,931,204 |
| November | 1,712 | 3,143,351 |
| December | 1,465 | 2,495,685 |
| January | 1,721 | 2,727,856 |
| February | 2,889 | 4,130,468 |

By far the greater number of motor trucks went to France, England and Canada, the remainder of the exportation being divided between over one hundred other countries. It is expected that later reports will indicate a similar ratio of increase.

**Tractors Popular in France.**—French agricultural experts and M. Thoumyre, under Secretary of State for Agriculture, announce the prospects for the wheat crop in France this autumn are excellent, according to the *London Mail*. More land has been put under cultivation and with the use of fertilizer and motor traction it is hoped that French soil will this harvest suffice to produce nearly all the corn needed for next year's consumption of bread. According to the official figures of the French Department of Agriculture this year five million hectares or over 12,350,000 acres of land have been plowed and sown with wheat. This should produce at least seventy million quintals of wheat, leaving about ten million to be imported. Last year the home crop was so small that more than thirty-five million quintals had to be imported. This bumper wheat crop is expected to save France the huge sum of six and one-quarter milliards of francs (one and one-quarter billion) and thus cause a considerable improvement in the value of the franc.

**Have Steam Cars a Future?**—Among pioneer motorists there have always been numbered a few enthusiastic supporters of the steam car. Despite the gradual disappearance of the steam car, that interest still exists, and it needs but the slightest encouragement to make itself manifest. Although the internal-combustion-engined passenger car seems to have ousted its rival—for only in the United States is the steam car still manufactured—yet recent developments in steam engineering, such as the oil-fired steamships and locomotive engines, suggest that were the steam car reintroduced on modern lines it would prove vastly superior in efficiency to its predecessors. At the present time the rising price of gasoline is focusing attention on alternative fuels, and it must be remembered that the steam car presents another method of utilizing kerosene and even crude oil as fuel. If we concede that a heavier grade of oil fuel than kerosene even, might be utilized in the light of experience gained from oil-fired furnaces, then it is conceivable that the steam car might be in a better position than formerly to compete against cars engined with internal combustion motors. This is, however, rather in the nature of conjecture, and we do not wish to raise false hopes in the breasts of the steam car enthusiasts as only one company is producing these cars on a really commercial scale. Others have been formed but the production has been limited to a few experimental models.

# Something Different in Salvaging Operations

## Relieving a Wreck of Its Cargo with the Aid of Injections of Compressed Air

By Robert G. Skerrett

IT is the unique thing in salvage procedure that makes it plain that the more or less deeply sunken craft is no longer a wreck to be classed off-hand as a total loss. Similarly, these occasional evidences of engineering resourcefulness show what the scientific mind is doing in the way of revolutionizing this department of human effort. And what is equally significant is that the skillful application of the force and buoyancy exerted by compressed air is making these advances possible. Probably no example of this is more instructive than the work recently done in raising and freeing the freighter, "Canadian Recruit," from a very difficult position.

The ship, a steamer belonging to the Canadian Government, sailed from Quebec in the latter part of December a year ago, and on her way seaward had to contend with heavy ice. As a consequence of her struggle to get clear she lost her rudder and was driven ashore. In the months that followed, the floes, impelled by the tides, shifted the vessel, and at the same time cut away the river bed under her stern, causing the ship to settle deeper there. She finally came to rest with her after deck 29 feet below the surface at low water and listed over to port at an angle of 18 degrees.

The run of wreckers along the St. Lawrence looked upon her recovery as exceedingly doubtful, but one concern having affiliations with United States experts essayed her refloating on a "no-cure, no-pay" basis. To make the problem harder, it should be pointed out that the steamer was stranded forward in shoal water, and she carried a general cargo which substantially filled her several holds. The "Canadian Recruit" is 250 feet long, has a beam of 43.5 feet, and a depth of 26 feet—a sizable craft.

The ship was hard and fast on Mille Vaches Shoals, where the tides run very strong and have a rise and fall of many feet; and to add to the difficulties the steamer lay in an exposed position with comparatively little water around her forward end for the prosecution of wrecking operations. Her release was primarily contingent upon the removal of much of her freight; and the nature of her cargo was such that it was well worth reclamation. Not only that, but because the stuff stowed aft was made up in part of many cases of glass bottles, ordinary dredging facilities could not be employed to clear the submerged hold. That is to say, had clam-shell buckets been used the bottles would have been smashed, and broken glass would have imperilled the divers at every step. Besides the boxes of bottles, the after cargo space held several hundred bales of hay, some tons of cement, more than 2,000 pieces of heavy lumber, and quite 8,000 bags of flour, rice, and malt.

The first problem was to get out the lumber and the flour, both of which floated and handicapped the divers continually; next it was essential to success that the rice and malt be sent up to the surface; and then, with the way cleared, the menacing glassware was carefully hoisted from the hold. And now we come to the first of the novel expedients resorted to in dealing with the problem. The flour, owing to its buoyancy, crowded upward in the cargo space and packed itself tightly in the upper section of the hold on the higher or starboard side and well above the lower projections of the hatch coamings. It was out of the question for the divers to pull these bags down several feet and shove them into the hatch openings so that they might rise thence to the surface. Accordingly, compressed air was fed into the upturned area in sufficient quantity to force the water level lower, and this enabled the divers then to push the bags of flour with comparative ease into the hatchways—their buoyancy serving to complete the rest of their journey upward.

But the malt and rice did not lend themselves to the same solution. Each package of malt weighed something like 200 pounds, and was held in two bags—the inner one being of a more closely woven fabric. Let it be recalled that tidal conditions were so troublesome that divers could work during the day but a maximum of four hours just before and after the slack of low water; and from their very nature the bags of malt and rice could not be dealt with quickly and in considerable numbers within so brief a span unless means could be devised to make them easier to move from where they were stowed to points vertically in line with the uncovered hatches. This was achieved by giving the bags, so to speak, hypodermic injections of compressed air—enough of this air being retained in the mass to make it slightly buoyant. In this condition the malt and rice could be shifted to positions whence they would float free to the surface. The "needle" for this work was fashioned of a short length of brass pipe pointed at the outer end so that it could be jabbed deeply into the package of malt or rice. The apparatus was fitted with a valve, and was connected to an air-supply hose. The double bags enveloping the malt and the glutinous condition of the wet rice immediately next to its container tended to confine the air for a while.

By reason of skillful use of this ingenious makeshift, this part of the cargo was disposed of rapidly. How thoroughly the men did their work under water is evidenced by the fact that when the "Canadian Recruit" was refloated only four bags out of a total of 4,500 remained inside of her.

With her after hold cleared and some of her cargo taken out forward—a considerable amount of it had to be left in to insure the craft's stability when again becoming water borne—the salvors displayed their highest skill in bringing the submerged after body up. The fore-and-aft trim of the steamer, her marked heel to port, the depth of water over her deck under the most favorable condition, and the sweep of strong currents made it impracticable to have recourse to cofferdams reaching from the hatches up above the surface of the St. Lawrence. There were no lifting vessels to be had capable of bodily raising the dead weight involved, even if wire hawsers could have been got under the wreck; and to seal her hatches and pump her cargo space full of compressed air was deemed too risky—the wreckers fearing that the expansion of the confined air, as the boat rose surfaceward and the hydrostatic pressure dropped, would blow up her decks unless rather complex measures for the relief of the air could be installed.

The means finally adopted were two steel trunks—really great metal boxes devoid of tops and bottoms, and fashioned large enough to slip freely into the two rectangular deck openings. At the top of each trunk there was attached a wide projecting brim or collar, and this had spread enough to reach beyond the hatch coaming. On the under side of this brim was secured a white pine plank, 3 inches thick, and upon this yielding material the trunk settled against the hatch coaming and was drawn tight by numerous hook bolts—thus providing an air-tight seal. The diagrams accompanying this article show how the trunks reached deep into the hold and were, in effect, in-turning bottle necks.

Their purpose was to permit the cargo space to be filled with buoyant air under pressure and yet to supply a medium for the automatic release of that pressure in a way that would not endanger the hull structure as the steamer lifted clear of the bottom—in short, to act as an elastic cushion capable of equalizing and balancing the opposing air and water columns.

Two channels were used for distributing compressed air in the after hold. One was a connection, made through the deck, to which hose was attached, and the other was a metal pipe, having an upturned or hooked

**Some of the ways in which the new alloy of magnesium is used for automotive parts**

## A New Magnesium Alloy for Motor Pistons

By George Gaulois

A NEW alloy of magnesium has appeared which is offered as the lightest metal to be used for pistons for automobile or airplane engines. It is the lightest metal known which is adapted to commercial uses. Magnesium constitutes ninety per cent of the alloy which differentiates sharply between this new alloy and other light alloys on the market which are made up mostly of aluminum and contain magnesium only in small quantities if at all. Some of the striking quantities of the new alloy, Dow metal, are due to the presence of magnesium which is the lightest metal possessing high tensile strength and physical properties rendering it suitable for engineering uses.

This new alloy has been brought to the attention of engineers within the last year. Prior to the war, magnesium was imported from Germany and its main, if not sole use, in the United States was as a deoxidizing agent for non-ferrous metals. The new alloy is one-fourth the weight of cast-iron and one-third lighter than aluminum. When the foreign supplies were cut off early in the war, the manufacture of metallic magnesium was undertaken at Midland, Mich., there being unlimited amounts of the raw material in the brine pumped from the numerous wells there, from which many other chemical products were manufactured. Among these manufactured products is the salt, magnesium chloride, which after suitable preparation is used for the manufacture of metallic magnesium. The process employed is electrolytic in which a heavy direct electric current is passed through a molten salt bath, maintained at a red heat until it is decomposed by the current and the metallic magnesium is formed which, on account of its extreme lightness, rises to the top, floats on the surface of the molten bath and is skimmed off from time to time.

In the past the demand for magnesium was limited, because no alloy of it had been discovered which possessed the mechanical properties necessary for its use in practical construction of the parts in automotive and aircraft production. But after much experimenting and after many tests, the present alloy was obtained. The main use found thus far has been in the manufacture of pistons for automobiles and airplanes, as well as motor boats. Possessing a tensile strength of from 22,000 to 25,000 pounds per square inch, it is also the lightest material used for such purpose, besides having no abrasive or scoring action on cast-iron cylinders and having approximately the same coefficient of expansion as other light piston alloys. This metal differs from aluminum as to the expansion under heat in a motor in that there is no permanent growth or set at these temperatures. Recent tests have shown that with 21 successive heats made for two hours each and for 0 to 800 deg. F. the permanent growth is so minute that it cannot be detected with a micrometer.

In machining no cutting compound is used and with the lathe running at the highest speed, there are no hard spots. Great resiliency is shown by recent tests at the Government laboratories at the McCook Aircraft Field, Dayton, Ohio, in which a piston was placed in a vise and forced in one-fourth inch and, upon being released from the vise, came back to size with the exception of being only 0.004 inch out of round.

The table gives the important physical properties:

| | |
|---|---|
| Specific gravity | 1.79 |
| Tensile strength, lb. per sq. in. | 22,000 to 25,000 |
| Yield point, lb. per sq. in. | 12,000 to 14,000 |
| Compressive strength, lb. per sq. in. | 45,000 |
| Elongation, 2 in., per cent | 3.5 |
| Reduction in area, per cent | 3.5 |
| Modulus of elasticity | 9,000,000 |
| Brinnell hardness | 55 to 75 |

## A Giant Ingot-Mold Casting in the Making

By A. R. Surface

ALL steel when made in any kind of furnace or by any process is poured into some kind of a mold. If the steel is later to be forged or rolled into some kind of shape it is poured into iron molds called "ingot molds." If it is to remain as a casting and used in the form in which it is poured or cast, it is poured in a sand mold and when cool, shaken out as a finished casting.

For some special forgings very large ingots of steel are required. This applies usually to large marine engine forgings or to propeller shafts, etc. Such an ingot mold for such a purpose and its method of manufacture is represented by the illustrations. It is of unusual dimensions and weight and its pouring and molding involved difficult problems, particularly as regards the core which forms the hollow part of the ingot mold and which corresponds to the steel ingot that is desired.

In order that a thoroughly sound casting might be obtained, it was poured on end. To accomplish this, the mold in which the casting was made was erected in a molding pit extending 14 feet below the floor level. Due to the fact that water is reached at 8 feet below the floor line, it was necessary to make this molding pit absolutely water tight. In pouring castings of this character on end, it is necessary to cast large risers or headers on the casting, so as to provide a quantity of metal upon which the casting itself draws as it cools, thus filling up holes caused by contraction. An experienced foundryman will appreciate the difficulties encountered in pouring on end a casting of this weight and character.

One of the important requirements was that the diameters of the mold should be the same at both ends.

# Aircraft of the Future

## A Statement of What Remains To Be Done, and the Directions in Which the Doing Seems to Lie

By C. H. Claudy

ACCORDING to their advertisements you can, for a dollar, get a "crystal reading" or a "spirit prophecy" or a "delineation of your future" from dozens of "mediums." According to universal human experience, prophecy goes wrong more often than it comes out according to specifications. So let it be said at the outset that this "delineation of the future" of the airplane is not intended as a prophecy but as a sober exposition of possibilities, based on a statement of the unsolved problems in aeronautics as formulated by no less a body than the National Advisory Committee for Aeronautics, instituted by Uncle Sam and transmitted in the form of an elaborate report to Congress by President Wilson.

If the future ever is foretellable in the way which will have credence from men of science, it will be merely as we foretell eclipses of the moon—by a thorough knowledge of the laws governing the phenomenon. It is a familiar truism that the unsolved problem of today is the commonplace of the morrow, always providing that the unsolved problem has a sufficient demand for solution to interest brains and money in its solving.

In spite of the fact that the United States is woefully backward in all that appertains to aviation, the world has demonstrated that the art of flight has come to stay and is to play a great part in peace as well as in war. The stern necessity to solve the unsolved problems of today will as inevitably solve them, as stern necessity devised the audion, ductile tungsten, the X-ray and a thousand other marvels. Simon Newcombe demonstrated mathematically that man could never fly a heavier-than-air machine. It was accepted as an axiom that the composition of the stars was unknowable—until Fraunhofer came on the scene. Always, when the demand has been great enough, we have solved our problems. To state, then, the problems yet unsolved is to foretell to some extent what the future may be.

### With What Shall We Build?

The committee lists as the first outstanding problem in airplane construction the matter of material. It lays down this as axiomatic: "We may, however, be well assured that however good may be any solution we may reach of the many problems presented to us in the industrial arts, there are, as a matter of fact, series of better ones only waiting our patient study." In other words, no matter how skilfully we use wood or metal or wood and metal to make a skeleton and fuselage, there are better ways and better combinations possible, and unknown possibilities in the use of new alloys, and some of the new steels of unheard of strength for their weight. That the optimum construction even with present materials has been reached is not admitted by the committee; that untouched fields in materials, forms, and combinations lie waiting the investigator is stated as a fact. It can then be predicated upon the whole history of construction of other bodies which must at the same time be strong and light, that the airplane of the future will be in all probability built of metal rather than of wood, and that its strength will be no less in proportion to its weight than today, and probably much greater.

The problem of materials is so closely bound up with the problem of size that the two can hardly be considered apart. The committee asks of size "Is there a limit? If so, what is it? Why is it? And how may it be removed or extended?" and then proceeds to answer itself by stating the factors of the size limit as we know them today. Weight increases as the cube, while areas of supporting surfaces increase as the square, or dimension. It seems obvious enough, then, that taking any given speed of plane and size of power plant as a standard, there must come a point when the whole cannot be made larger without becoming too heavy to fly.

### The Problem of Size

*Yet these same laws obtained when Wright first flew in a forty-foot plane, and when the huge Capronis of today were not even dreamed of.* We have escaped this law so far and there seems no reason to think we may not continue to escape it. We escape it by the simple trick of not enlarging our planes as a whole. We do not make a big plane line for line like a small one. We do not have to make a large wing geometrically similar to a small one. We can lighten as we enlarge; lattice takes the place of solid, tube replaces rod. Moreover, the wing, which supports, weighs least of any of the three great members of a plane—wing, fuselage and power plant. We may extend wing area and get increased lift without even squaring, let alone cubing, the weight—if we can engine the whole. If we can master the aerodynamic problem of multiplying wings without interfering the one with the other, there may be no limit to the size of our future planes.

We can safely prophesy, then, that when the demand comes for a huge plane, capable of carrying not its tens and twenties but its hundreds of people, not its ton or ten tons but perhaps its hundreds of tons of weight, there is no structural or scientific reason why that size should not be had. In other words, the plane of the future will be to the plane of today what the "Leviathan" of the sea of today is to the "Clermont" of yesterday.

No one familiar with airplanes of today who knows that as speed increases wing areas diminish, and that as wing areas increase speed diminishes, but understands the real need for some practical plane of wing-area variation during flight. A very high-speed machine is a dangerous thing when it comes to landing if the field is not huge and smooth, because it must land at high speed. A plane that lands safely on fairly rough ground can accomplish little in speed. Either variable areas or variable camber (curvature), or both, may easily be accomplished upon the designer's board or in model form, but so far no wholly practical solution of the problem in actual machines has been attained.

It seems obvious, therefore, to say that the plane of the future will have the speed of the high-speed planes of today and the safety and slowness of low-speed planes of today, at will. Indeed, a completely successful variable-area and variable-camber wing outfit would probably solve the problem of the landing field and permit landings in small spaces, perhaps even upon the roofs of city buildings, and yet with safety.

### The Engine and the Fuel

The problem of motive power is in a constant state of flux. No consideration can be given to it without drawing an immediate dividing line between the probable and the possible. The probable power of the future in the light of the present is an internal combustion engine presumably burning gasoline or other light volatile liquid. The possible powers are numerous—wireless power, electric power, liquid gas power, high-explosive power, steam power, bithermal power—all these are possible in the sense that they are yet largely untried. The committee confines its attention to the probable development of existing airplane engines, and lists among the main outstanding engine problems the problem of fuel, the problem of how much power to an engine, of how powerful a power plant may be, the carburetor, of ignition systems and of maintenance of power at high altitude. The committee finds that the present-day refined motor fuel for aviation engines nearly approaches the ideal; "a long look ahead shows that a serious problem must be met before many decades," and the committee makes no suggestion in regard to what will happen "when present petroleum sources will no longer yield the supply we now use."

"How much power can we put in an airplane? How much power from a single cylinder? A single engine? A single airship?" The committee sees nothing in the way of multiplication of cylinders in one engine up to eighteen, and nothing in the way of multiplication of engines even beyond four. It does not believe much more than forty horse-power per cylinder can be developed along present lines or that cylinders can become much larger but figures that if a 2,500-horse-power power plant is called for, it could be designed (several engines) and that even larger collections might be possible. It defines the limitation largely as a problem of cooling, but it seems safe to state that the airplane of the future will have all the power it needs unless, indeed, its needs become Gargantuan beyond present-day visions of possibilities. None foresaw the enormous horse-power of ocean vessels of today when steam was first applied to ship, or of locomotives when the Rocket first puffed her uneven way, or of automobiles when Daimler first chugged in his one-lung vehicle.

### Mixing the Fuel and Touching It Off

The carburetor is still an unsolved problem for the automobile: much more so for the airplane, which changes its level by thousands of feet. That the airplane of the future will be independent of pressure and chemical-constitution-of-the-air variations due to altitude seems unquestionable. Whether by forced air feed or an oxygen tank or some other method must be left to the future to decide. Whatever the solution the carburetor of the future will function as well at high altitudes as at low ones, will supply an even mixture for each and all of any multiplicity of cylinders, and an even quantity of mixture to each cylinder, will not be affected by changes in inclination and will be accident-proof, that no failures occur in mid-air.

Ignition is still a problem, strange though the word sounds to those who marvel at the perfection of generator, battery, magneto, wiring diagram and spark plugs of today. The committee says: "If we can anticipate the explosion engine of the year 1970, assuming that our grandchildren are still dependent upon hydrocarbon fuels at that date, it would seem as though some more simple and direct mode of initiating the combustion in the cylinders would have been found. On the law of probability the chances are overwhelmingly against our having at the present moment developed the very best method of ignition." This would seem to presage some sort of thermal tube, or even ignition by compression, *à la* Diesel engine, but the present scribe ventures no further than to state the apparent fact that the airplane engine of the far future will not depend upon a complicated and delicate electrical system to fire the charges in its system—at least not if careful research can find a better and simpler way.

### Divorcing Power from Altitude

An airplane normally loses horizontal speed as it ascends to higher altitudes. The reason is in the one factor which remains fixed while everything else changes with altitude. That one factor is the weight which, while it does change mathematically with removal of the mass from the center of the earth, does not change practically. While decreased supporting power of the air (due to its rarity) is compensated for by decreased resistance as far as headway is concerned, it is nevertheless true that the weight, remaining the same, must be kept up in the more rare medium by a greater angle of attack of the wings upon the air, which, drawing from a fixed amount of power, requires more power for translation into weight support and leaves less for propulsive effort. Moreover, while the same amount of cubic-inch displacement remains in each cylinder regardless of altitude, what goes into the displacement is less and less as altitude gets greater and greater. The plane which is normal-powered for low altitudes is under-powered for high altitudes. That some solution will be found, either in design or in the use of air compressors, seems obvious. Certainly the airplane of the future is not to be handicapped by

(*Continued on page 532*)

*SCIENTIFIC prophecy is frequently referred to as a very dangerous game. Under some circumstances it is dangerous enough, for, as we have recently pointed out, if the scribe knew the direction in which the ship of discovery ought to be piloted for greatest success, he would be at the helm instead of on the dock awaiting her return. But Mr. Claudy exhibits the other side of the picture when he reminds us that in many cases a mere statement of the problems unsolved is apt to be a pretty definite forecast of the direction to be taken by the effort at solution. Especially is this the case in an art so definitely mechanical as that of flying. So we feel that Mr. Claudy's remarks should perhaps be taken a little more seriously than we are accustomed to take the scientific prophet. The airship of the future must exhibit many of the features which he suggests.*—THE EDITOR.

# The Five States of Matter

## Two Fundamental Conditions That Must Be Recognized, Besides the Solid, Liquid and Gaseous

MATTER may be defined as that which occupies space, possessing therefore comparative weight. This definition does not denote the physical characteristics of matter, but it is now generally conceived to be capable of existing in five specific forms, each having its own characteristics but capable of assuming the characteristics of another state under certain definite conditions.

The physical properties of three of the five states of matter, namely, the solid, liquid and gaseous, are so well known that only a concise mention need be made concerning them, says the *Bulletin* of the International Metallurgical and Chemical Society. Regarding the other two states, radiant and ionic, less is known concerning their physical identity and characteristics, so that it becomes necessary to study them through the phenomena that they are capable of exhibiting, and not through themselves. This may seem strange to say, or it may appear contradictory, insofar as previously stated that matter must have weight, whereas we cannot study radiant and ionic matter directly, but through the characteristics that they possess. When studying electricity, we do not study it directly, but study the effects of it.

The most recent investigations and researches dealing with the nature of matter, point in the direction of the electrical identity; that electrical charges, both negative and positive, are the cause of and constitute all matter. Now matter must possess weight (truly), so that if matter is composed of that phenomenon known as electricity, why, the source of it must possess weight in the first place. Briefly stated in the words of that great scientist, Benj. W. Sands, "what equals one thing must equal another." If the essentials of the electrical theories of matter are held as probable (and there is no doubt but what they are as reasonable expositions of matter as the accepted atomic and molecular theories), the relation and interrelation of the various states can be readily accounted for, together with the correlation of energy and many other phenomena which previously were considered complete or veiled mysteries.

The importance of a thorough investigation and understanding of matter from a chemical aspect cannot be overestimated. First, chemistry is the science which deals with matter (the elements, their compounds, mixtures and characteristics); in the second place, chemical reactions and interreactions can account for many of the phenomena which formerly were considered purely physical; then in the third place, in order to understand energy and the correlation of the forces, it is necessary that a solid foundation be established concerning matter, and its cause. When one fact concerning matter or its cause is firmly established, we have a basis from which to work and investigate further.

*Solids.*—A solid substance is a body at ordinary temperature and pressure which can retain its original shape to a limited extent.

"A solid is a body which, at ordinary temperature and under slight pressure, does not change its shape." —Hoadley.

*Liquids.*—Liquids or fluids are bodies which, upon slight pressure upon the surface, give way in the immediate vicinity. Liquids have definite size, but they take the shape of the container and have a free surface.—Carhart-Chute.

*Gases.*—Gases are bodies which are in suspension, being neither solids nor liquids. Gases possess some of the qualities of both solids and liquids; *i.e.*, they cohere, and give way under pressure.

A gas is a body whose internal forces do not constrain it to assume any definite volume or form. It expands in all directions. . . . When confined in a closed vessel, it exerts pressure upon every part of the surface which envelops it.—Magie.

*Radiant.*—Radiant matter is that which is existing capable of being transferred from one substance to another, or being condensed and focused. Light and heat are the two most common occurrences of radiant matter. Of course the argument that is still advanced that light is not heat, may be considered, but the fact that radiant heat traverses space with the same velocity as light tends to disprove that theory, so that with great probability, if not certainty, light and heat may be considered radiant matter or varieties of it. One of the characteristics of the radiant state is that it is capable of passing through certain substances without being perceptibly absorbed. This is not a true scientific statement, insofar as probably there are no bodies that are perfectly diathermanic.

*Ionic.*—Ionic matter is capable of being transferred through space without changing its natural state. It is capable of existing anywhere and might be termed etheric or kinetic matter. It is the unity atom, potential matter, or the protyle of Sir William Crookes. It is the cause of the evolution, or genesis, of the elements, together with its accompanying phenomena. It is the electrical phenomenon responsible for all matter.

It differs from the other four states, as it is invisible, so indefinitely small that it possesses the property of being able to penetrate all other matter, but still so great in latent properties that under certain conditions it is responsible for other conditions and states of matter.

As is noted, the differences between the five states of matter are very indefinite, in fact, so obscure that they terminate into each other. It is similar to those (literal) changes of matter which some state are physical and others chemical. However, when the true nature of these changes is understood, it is probable that it will be able to account for these properties.

In studying the states of matter, the idea of the law of periodicity or the cycle law, such as has been demonstrated by Mendelieff and Meyer, in the formulation of the periodic table through the grading of atomic weights, and by Sir William Crookes, through his differentiations of protyle by means of the vibration frequency and space of the hydrogen atom, has been forced to be taken into due consideration. To illustrate the law of periodicity or scientific equality, if the ionic state of matter is responsible for the radiant state, the radiant for the gaseous state, the gaseous for the liquid state, the liquid for the solid state, could not this process be reversed when the last named state is reached and it be responsible for the ionic state, therefore a cyclic process? Or upon the hypothesis of Sir William Crookes, the unity atom being hydrogen (?), the differentiation of the elements and its various states can readily be explained.

### Power from the Thermocouple

To the Editor of the SCIENTIFIC AMERICAN:

I have noticed in several recent issues of the SCIENTIFIC AMERICAN and of the SCIENTIFIC AMERICAN MONTHLY articles relating to the approaching time when our visible fuel reserves will be exhausted. One article in particular whose title and author I do not remember, mentioned the sun, the tides, the internal heat of the earth, the wind and water power as being sources from which we can draw our power and heat in the future.

We all know of the experiments which have been conducted in Egypt and elsewhere in the generation of steam from the ordinary heat of the sun concentrated by mirrors or lenses upon a boiler. The chief difficulty of this lies in its inefficiency and in the large and expensive layout necessary in proportion to the power secured.

It has frequently occurred to me that the principle of the thermal couple could be utilized to advantage in turning the sun's heat directly into electric current, eliminating much of the heavy complicated machinery now necessary to do the work.

The thermal couple as it now stands is of course extremely inefficient; though I do not think it is more so than were the earliest motor generators; and it would probably not be impossible to develop it to compare favorably with motor generators of today in efficiency. It is at any rate a promising field for research and experiment. A large number of such couples could be connected in parallel, the joints being flattened to receive the sun's heat from a wider area and sheltered from wind to prevent any cooling effect. The cooled joints might be buried deep in the earth or cooled by running water or in any of a variety of ways. Extensive plants could be erected on the deserts of Nevada and Utah and current transmitted on high tension lines to neighboring cities. Or it might be that Marconi's suggestion of wireless transmission of power could be developed so as to be used to advantage.

At any rate there is approximately a horse-power in sun's heat going to waste on every square yard of that desert country, which would be well worth going after.

In regard to the use of the wind as a source of power the writer of the article above referred to made the objection that a windmill which is strong enough to stand up against heavy gales is too cumbersome to be moved by light breezes. While this is perfectly true of the ordinary type of windmill it is still possible to construct a wind-power machine which is neither too heavy for the lighter breezes nor too weak to resist the heavy gales. I know of two general types of machine which would satisfy these requirements, one being on the order of the centrifugal blower which is used to ventilate our large industrial plants, the other being in the form of a helical screw upon an axis fixed in a tube with a flaring mouth to concentrate and increase the velocity of the wind in the tube. This flaring mouthpiece could be used upon any type of wind machine and would have the same effect of an increased diameter of wheel without adding to the weight of the moving parts. Automatic arrangement could be made whereby it would be removed or rendered non-effective when the wind reached a pre-determined velocity. There are a number of other ways in which a battery of wind machines could be regulated so as to produce a fairly constant current.

These are suggestions which may be of interest to any of your readers who are equipped for research work along these lines.

New York. LEO G. HALL.

### Two Problems That Are With Us

To the Editor of the SCIENTIFIC AMERICAN:

I have been very much interested in the Einstein theory, but have not been able to learn much about it except through a few popular articles that were not written by any of the famous twelve. I hope that in the articles that I understand you are going to publish on this subject that you will not bury the facts under the mass of glittering generalities that befog most "popular expositions."

This seems to me to be a suitable time to add a few remarks to the many that have already been said about Mars. Starting from the supposition that the inhabitants of Mars differ from us no more than the Chinese do, there would still be no possible way to prove that any signals that might be exchanged were the result of intelligence and not the accidental working of nature. The only way communication can be established that would defy argument would be for some person actually to visit Mars, the arrangements for the trip being under the auspices of some institution whose prestige would be a guarantee against trickery. Such a trip is not impossible but the difficulties in the way would probably prevent its accomplishment at present.

Camp Lewis, Wash. CAPT. A. R. ROCKWOOD, C.A.C.

### Twins

To the Editor of the SCIENTIFIC AMERICAN:

In discourses on heredity I have often seen it mentioned that the tendency to have twins is hereditary, or "runs in families"; but there is what appears to be another fact regarding the twins tendency that I have never seen in print and hence doubt that scientists have noted it. This fact is, that the mother of twins will almost always be found to have had an unusually large number of brothers or sisters or both; while the father in a good many cases may have had but few or none. As local registrar of births and as a member of this community for many years, I have been unable to find a single instance in which a mother of twins did not have at least five and sometimes about ten brothers and sisters. This I think could hardly be mere coincidence, and I ask that scientists look into the matter, for it is something that could be easily proved or disproved.

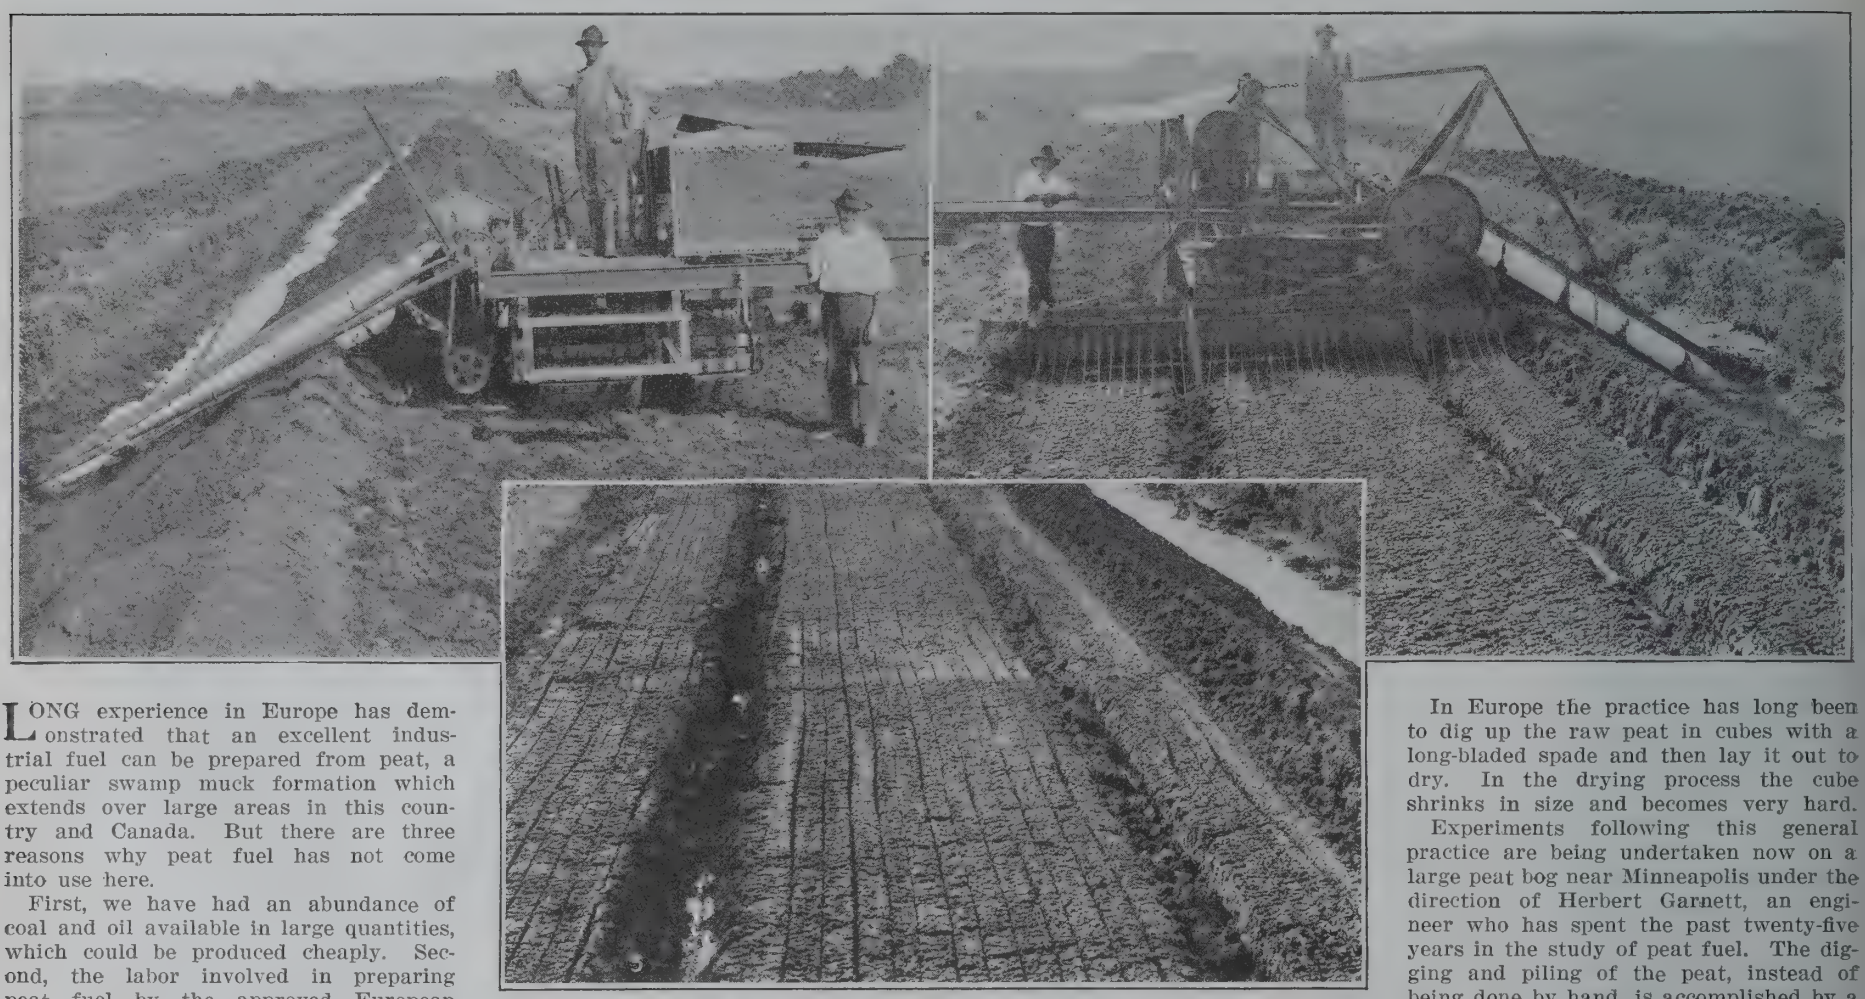
Livermore, Cal. ELMER G. STILL.

[*We know one case where the mother of twins is herself one of five; but this is hardly enough to throw Mr. Still out of court. If any reader wishes to put other cases before Mr. Still the printed address will reach him.*—THE EDITOR.]

# Our Coal in the Making

## America's Peat Bogs and Their Utilization for Fuel

By Harry A. Mount



1. The peat digging and spreading machine, seen from the direction toward which it is progressing. 2. Another view of the machine, from behind, showing the cutters that leave the peat in strips. 3. The bank of peat left in the wake of the spreader

**How peat is being taken out of Minnesota's bogs by machine**

LONG experience in Europe has demonstrated that an excellent industrial fuel can be prepared from peat, a peculiar swamp muck formation which extends over large areas in this country and Canada. But there are three reasons why peat fuel has not come into use here.

First, we have had an abundance of coal and oil available in large quantities, which could be produced cheaply. Second, the labor involved in preparing peat fuel by the approved European method makes it impractical for adoption here. Third, we have lacked adequate machinery for easily converting large quantities of peat into fuel.

As a natural result of these, might be added a fourth reason. Our industrial engineers know little or nothing of the properties of peat fuel and the "technique" of its use has yet to be developed.

The real reason, of course, is our hitherto "inexhaustible" supply of coal. But hardly a day passes now that we are not presented with some new evidence that our coal supply is far from being inexhaustible, and indeed our present supply barely can be stretched to meet our increasing industrial needs. And so our engineers have already turned their attention to peat and the limited development which has taken place holds the promise that before many years we may expect to see our 12,000 square miles of peat deposits supply fuel for many of our factories and utilities, and even our homes.

The files of our patent office bear witness to the fact that many attempts have been made to manufacture peat fuel by a purely mechanical process. These have all been failures because of the nature of the raw peat, which was not thoroughly understood.

True peat is really coal in the making. It consists of age-old deposits of ferns and water plants which have gradually built up a lake into a swamp. The deposit consists largely of partially decayed water plants, which naturally have a large affinity for water.

Raw peat may contain as high as 90 per cent moisture and so far every effort at mechanical elimination of this water has failed, from a commercial standpoint, due to the fact that about 60 per cent of the moisture is held in chemical combination or in minute cells.

The water can be eliminated in mechanical dryers, but more fuel is required to drive off the moisture than the finished product furnishes. Only a small part of the water can be forced out under the most powerful hydraulic press.

The most successful method of elimination, and that used most widely, is the ordinary process of sun drying. About ninety days, however, are required to dry the peat to 20 per cent moisture, when it is suitable for fuel. Operations, moreover, are necessarily restricted to the summer months and to dry weather.

In Europe the practice has long been to dig up the raw peat in cubes with a long-bladed spade and then lay it out to dry. In the drying process the cube shrinks in size and becomes very hard.

Experiments following this general practice are being undertaken now on a large peat bog near Minneapolis under the direction of Herbert Garnett, an engineer who has spent the past twenty-five years in the study of peat fuel. The digging and piling of the peat, instead of being done by hand, is accomplished by a specially designed machine, photographs of which are shown herewith.

The machine digs to a depth of seven feet, the sides of the bank sloping at an angle of 60 degrees. The digging unit consists of a special type worm, having double flights rotating against the direction of travel of the machine. Thus the original structure of the peat is destroyed, the lower layers being mixed with the upper, and the whole mass is delivered into a macerator at a uniform consistency. The macerator consists of rotating knives which further break up the fibers and cell structure of the peat and then the pulpy mass is discharged to the ground just in front of the spreader.

The spreader moves the mass over from the excavation and spreads it in an even layer about four inches thick, the sheet being upward of sixteen feet wide. The sheet is cut into strips as the machine moves along by the cutters as shown in the photograph and it is afterward cross cut by a device not shown.

In each cubic foot of peat as it lies in the bog there is from 10 to 15 pounds of dry fuel, so a large bulk of material must be excavated to produce a ton of fuel—roughly, 7 cubic yards are required. The for-

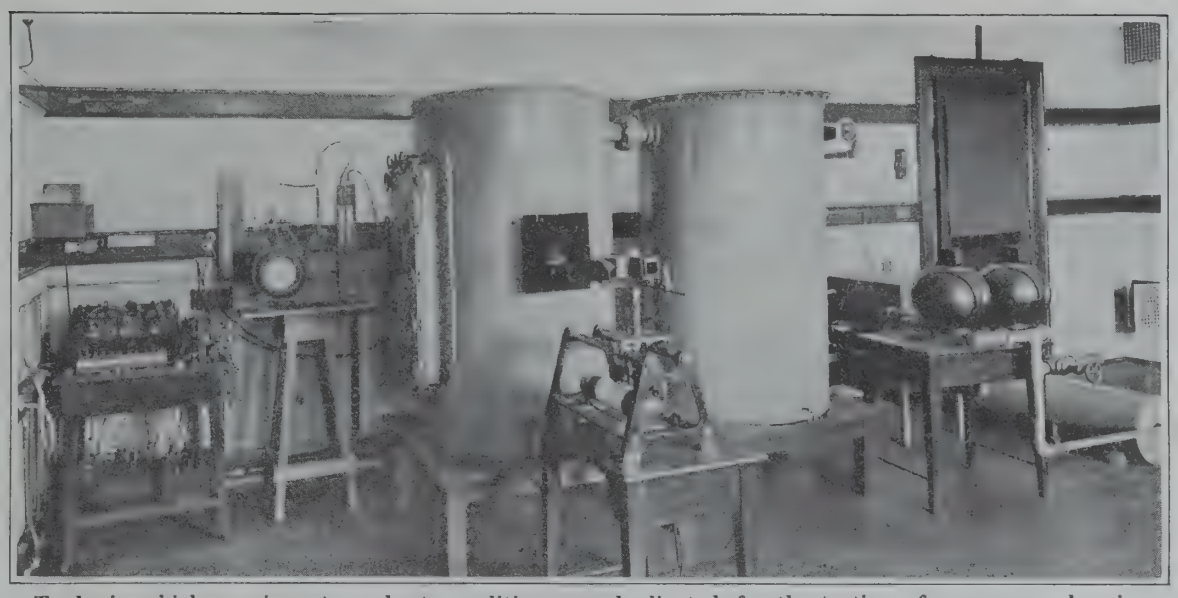
## The Atmospheric Tank

TANKS equipped by the National Bureau of Standards are capable of duplicating atmospheric conditions, varying from the driest spell in January to the wettest day in July, as a medium of determining the influence of atmospheric pressure and moisture on the candlepower of gas flames, gas mantels, and kerosene lamps. What effect does a rainy day have on the gas flame or kerosene lamp in your home? is an inquiry not outside the province of this government apparatus.

A constant flow of air at any specified pressure is maintained through the tanks, ranging from pressures of two-thirds to one and one-third times atmospheric pressure. The moisture can be controlled so as to duplicate conditions anywhere between parching aridity and a superabundance of rain. The intensity of the light of the gas flame or kerosene lamp is measured through a glass window in the side of one of the tanks.—By *S. R. Winters.*



**Tanks in which varying atmospheric conditions are duplicated, for the testing of pressure and moisture effects on the candle-power of gas and kerosene flames**

## Producer Gas from Harvest Waste

"CONSERVATION in waste places" is truly a shibboleth all-pervading in its grasp. The evidence is cumulative, the latest innovation being the utilization of wheat, oat, and rye straws in producing gas. The distilled product is the result of tests at the experimental farm of the United States Department of Agriculture at Arlington, Va. An automobile has been propelled with the new combustible and it has been employed for illuminating purposes as well as for cooking. The commercial possibilities of straw gas, however, have not been determined.

The government experiments will relate to the quantity and quality of gas as distilled from wheat, oat, barley, rye, and rice straws, and from cornstalks, corncobs, and other vegetable material hitherto classified as waste. If the scientific investigations at the government farm develop the anticipated commercial possibilities of straw gas, equipment will be devised to facilitate its production by individual farmers. The gas could be utilized in supplying light and heat for the farm home, power for stationary engines, and, possibly, fuel in operating the tractor. Its economic value would thereby be established, conserving raw material frequently burned or permitted to rot in the fields. The supply in the West and Northwest would be practically limitless.

Fifty pounds of straw will yield about 300 cubic feet of gas. Converted into power for propelling an automobile, a light roadster can go 15 miles on 50 pounds of straw. At present, the immediate problem is in the conversion of straw gas into liquid form or condensing it as a possible motor fuel. Among the by-products obtained in the manufacture of gas is carbon residue suitable for making lamp black of fine quality. Likewise, this residue contains limited quantities of potash, phosphates, and nitrogenous compounds of fertilizing value. The tar and ammoniacal liquids resulting from the process, aside from their value as disinfectants and preservatives, may be useful in the dye industry.

Straw gas is not brand new, the process being developed by George Harrison, a Canadian engineer at Moosejaw. The University of Saskatchewan, Canada, installed a straw gas equipment, which was later purchased by the United States Department of Agriculture. The Canadian scientists succeeded in operating an automobile with the product, the fuel supply being transported in a large flexible bag on top of the car. The method, in spite of its wide war-time use in Europe, smacks of impracticability. Still, it may be possible to put straw to some practical use sooner or later.—By *S. R. Winters.*

**Charging a retort with straw for the manufacture of gas**

## The Centrifugal Oyster

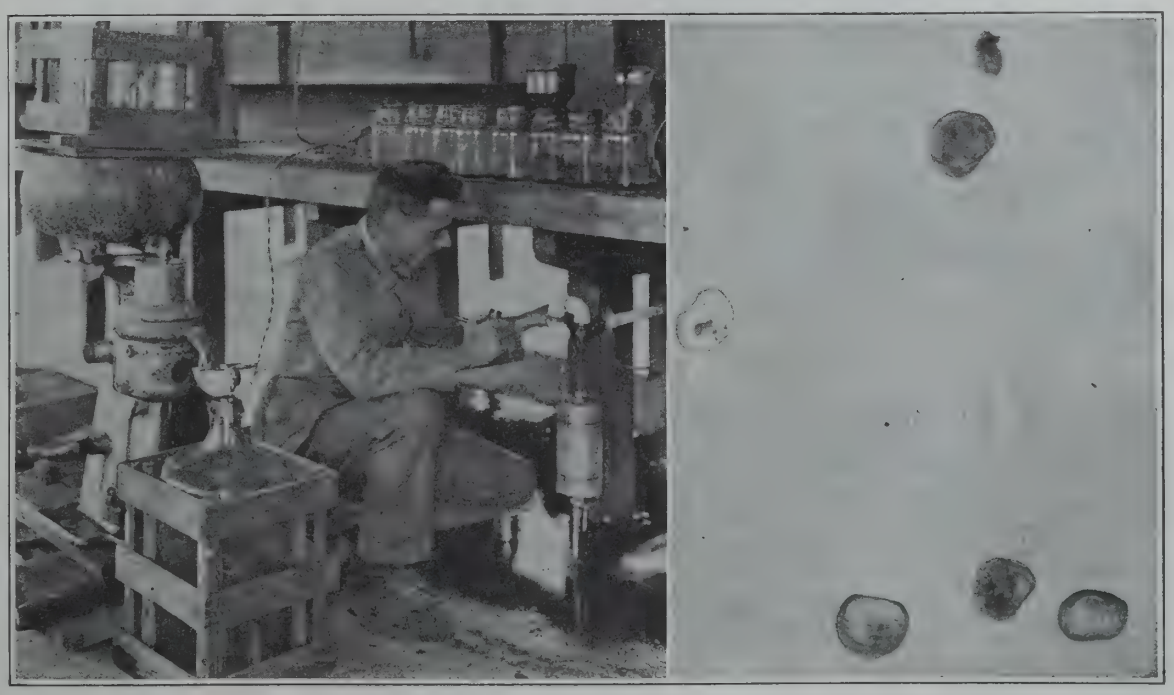
SALVATION of New York's declining oyster industry is promised as a result of the first successful experiments in the artificial propagation of oysters, which have just been completed by W. F. Wells, biologist and sanitarian of the New York State Conservation Commission. The work is part of the broad program for the fullest possible use of the State's natural waters, which is being pushed by the Conservation Commission with every promise of worth while results.

It is a well-known fact that the yield of commercial oysters in the northern and eastern waters has been gradually shrinking within recent years, the main cause of the decline being the continuous and unexplained failure of the oystermen to secure a "set" of young oysters. By "set" the oystermen refer to the habit of young oysters shortly after they have been hatched of sinking to the bottom and attaching themselves to shells and other smooth objects. Once "set" the oysterman can shift his oysters to suitable "growing" and "fattening" grounds, but if the young oysters do not attach themselves to the shells which the oysterman deposits for that purpose, his business naturally fails.

The important facts of Mr. Wells' experiments, which he has been carrying on in an improvised laboratory at West Sayville, L. I., are that he has succeeded in obtaining eggs from oysters and fertilizing them in much the same way as is done with fish in hatcheries, and has then been able artificially to feed and raise the young oysters until they have "set"—a thing which has never been accomplished before. The far-reaching significance of this achievement can readily be seen in the possibility of establishing vast oyster beds in suitable waters from "sets" of young oysters that have been artificially secured. As a single oyster will discharge from 10,000,000 to 100,000,000 eggs each season, the day may be not far off when oysters may come to be a common food of the people instead of being gradually forced into the class of a luxury for the epicure through a failing supply.

The success of Mr. Wells' experiment, where others have failed, has been in the ingenuity with which he has provided fresh food and water for his microscopic charges. Previous investigators have frankly admitted that they could devise no means of changing the water without losing the minute forms, which have consequently started before reaching the "setting" stage. Mr. Wells has overcome this difficulty by using a centrifugal machine, and in this way concentrating millions of little oysters from a large volume of water into a small bowl. They could then be transferred to fresh water containing food and other living necessities. At first it might appear that such delicate animals would be injured by passing through a centrifugal machine, but, being enclosed in shells, which act as a protection, Mr. Wells found that they could be concentrated in the machine without any injury.

About one month after hatching, the little oysters, which are free swimmers during that period, adhere to shells and even "set" in large numbers on the glass sides of the receptacles.



*Left:* Centrifugal machine in which microscopic eggs are separated from the water when it is necessary to change the latter, and glass jars for transferring the resultant "concentrate." *Right:* 14-day-old oysters magnified 100 diameters

# Taming the River Nile

## Construction of Dams and a 225-Mile Canal to Double the Irrigated Area in Egypt

By H. C. Hardy

IT will come as a shock to many proud Americans to know that neither the enormous irrigation project of our far-famous Reclamation Service nor the Panama Canal is destined to remain the largest man-made water works in the world. Egypt, ancient home of the art of irrigation, is to come into its own with an irrigation system which will make ours small by comparison and dwarf the great Aswan (used to be Assuan) storage dam as the Panama Canal dwarfed the Erie.

The matter is of especial interest to us, however, from the fact that in the settlement of the principles which had to be enunciated before this great enterprise could be carried out, an American engineer had a leading part, and because of this settlement a principle of equity in water was enunciated which may have a very large part to play in the relations of the United States with its neighbors, Mexico and Canada.

Most readers are familiar with the part the Nile plays in Egypt; so intimately interwoven with the land of the Pharaohs and the cradle of civilization is its great river that literature and history are filled with it. Thoroughly to understand the present great project, however, it is necessary clearly to visualize not only the Nile as a river, but as a source of irrigation.

An Egyptian cotton field, the main reason for the great irrigation project

The huge river has an average difference between mean and flood water of twenty-five feet. During flood water, since the memory of man runneth not to the contrary, it has been the custom of the Egyptians to cut canals through the banks of the river, draw the water off into the valley of the Nile where it is confined in basins, there to settle and deposit its rich alluvial silt, and later to be allowed to flow back again into the river, less that lost by evaporation and sunk deep into the soil. In a rainless country, the water thus remaining in the unusually rich soil deposited, grows crops with speed and profusion.

The more Nile water which can be used, the greater the area which can be flooded, the more crops which can be grown, the greater the income to both the people and the State (since there is but one tax in Egypt and that upon the land irrigated). No water, no irrigation; no irrigation, no tax. A low-flood Nile has meant famine and starvation and a depleted treasury; a high-flood Nile has meant plenty and great crops and a full treasury as far back through the past as the records of our oldest civilization go.

But, as was natural to an agricultural people who knew nothing of irrigation as a science, the native Egyptian methods are wasteful and inefficient. Moreover, the most profitable of all crops, cotton, must be planted early in the year, at the time of low water, and for cotton continual irrigation is necessary, not merely one period, such as suffices for the maize and grain crops.

To produce water for cotton raising during the period of Nile low water, a great barrage (we should call it a division weir) was constructed twenty miles below Cairo by French engineers. It was supposed to raise the level of the Nile at least fourteen feet, but because of the lack of a firm foundation on which to build and the lack of knowledge of irrigation work at that period, the structure bulged in the middle, cracked, and could safely be used only for a raise of three feet of water. This was in 1880. In 1882 the Allied powers took charge of the chaotic finances of Egypt and English engineers put down a flat weir below the French works, relieving the strain and making the French weir to some extent useful.

The year 1885 saw the long staple cotton crop, which grows only in Egypt and in one small velley in this country, well begun. This long cotton is three times the value of ordinary cotton and of huge profit to the land of Egypt as well as the State. Naturally Egypt wanted to use more and more water at times of low water to grow the crop which brought wealth to both country and grower.

The eminent English engineer, Sir William Willcocks, suggested the great storage dam at Aswan, at the lowest cataract of the Nile, which was begun in 1903. But it was not built as high as he wanted it built because of entirely sentimental reasons—the little island of Philae has upon it a wonderful old ruined temple, which was held by many to be of more importance than irrigation or cotton. To build the dam too high would be to cover the island and the temple. Let no one laugh who reads—the reformer we have always with us and Niagara is, and probably always will be, a bone of contention between the beauty lover on the one hand and the electric industries engineer upon the other.

However, time brings changes and time brought an ever increasing demand for water. Great as was the Aswan dam, it was not great enough, even after it was raised in 1912, to a sufficient height to cover Philae at high water and immerse the temple beloved of historians and archaeologists. Egypt planted more and more cotton and demanded more and more water from low-flood Nile in the spring. There were two and a half billion cubic meters of water backed up behind Aswan dam—two million acre-feet of water, all useful save the twenty per cent lost in evaporation. But it was not enough, especially was it not enough when the war began to demand cotton, cotton and still more cotton, for its textiles and its explosives.

Sir William Willcocks suggested a still higher dam, below Aswan. Sir Murdoch MacDonald devised a plan to build dams above Khartoum on both the Blue Nile and the White Nile, thus going into the Soudan for water, a plan which also included the irrigation from the Blue Nile of three million acres in the Soudan.

To use the White Nile as a source for

## Keeping Tabs on Bird Peculiarities

**By George H. Dacy**

"AND the birds of the air, they labor not, neither do they spin, yet they know when the summer is nigh," is a Biblical excerpt which appropriately presents our lack of knowledge concerning the everyday doings of the myriads of native birds and which accurately describes their remarkable migratory instincts. Heretofore, sporadic and unsystematic efforts have been attempted on the part of unorganized and indivilual bird lovers and fanciers to ascertain some definite facts and figures on the goings, comings and everyday activities of the birds of their localities. These investigations were, to a certain extent, centralized eleven years ago when the American Bird Banding Association was organized. The recent absorption of this work by the United States Bureau of Biological Survey promises a marked and potential expansion of the investigational activities.

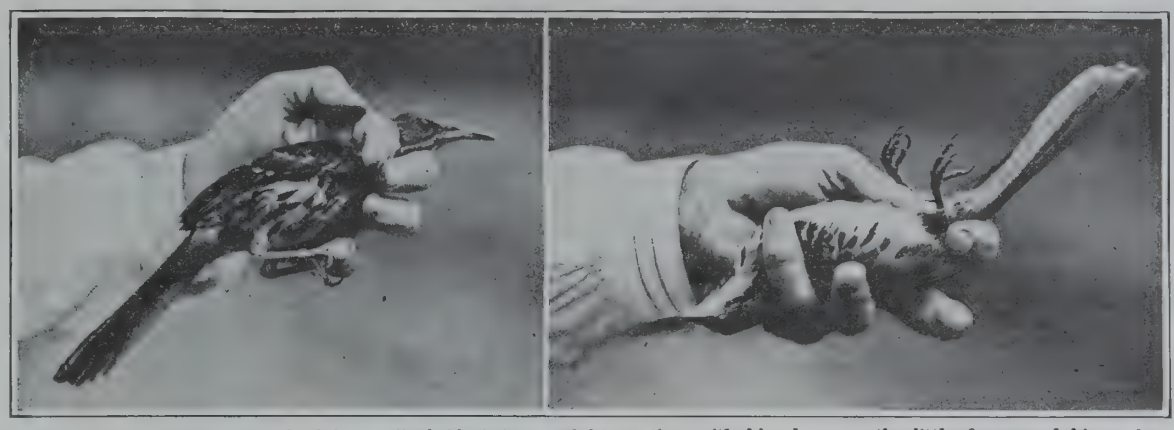
By the systematic trapping and banding of birds for identification purposes, it is possible accurately to keep tabs on the potential operations of a limited number of these birds which react favorably to trapping and which soon acquire the habit of returning, season after season, to the same feeding stations where they were originally caught. A bird soon learns that it is always assured of a square meal every time it visits the feeding station and that it will be given its freedom again after being fed and examined. Some birds such as the cardinals actually become obnoxious around the traps, remaining in the neighborhood continuously, entering the traps and preventing the entrance of other birds. In a word, the free meal idea appeals to the cardinal and, whenever possible, this tramp of the bird family avails himself of lunches of this description.

The English sparrow trap—originated by the national Department of Agriculture for the capture of such marauders wherever they became objectionable and injurious to crop culture—is used chiefly in snaring the wild birds. The trap is ordinarily baited with finely cracked grain such as commonly is sold as baby chick food. The grain is scattered thinly as far as five feet from the trap while crusts of bread are spread inside the wire cage. In the majority of cases the trap is placed on the ground and surrounded by a guard fence of chicken wire about 60 feet in circumference to protect it from the neighborhood cats and pet dogs. Only where it is desired to capture the birds which live in the tree tops is the trap ever placed in a tree.

The preferable time of the year to catch the birds is during their migrations or after they have established their residences for the season, although in most instances the birds respond to the bait at most any period after they have once been trapped. When a bird is captured for the first time, the bird lover should place a small identification band around the leg of the bird. The bands in use at present bear the inscription "Serial Number——, Notify Biological Survey" on one side and "Washington, D. C." on the other. In applying the band it is necessary to hold the bird firmly but gently so that it cannot flutter.

In cautioning the novitiates in bird study about handling the little fliers, a bird expert makes the following suggestions: "For examination, the bird is best held sitting upright, resting with his claws on the little finger, and with his neck between the first and second fingers. In this position the bird will rest placidly, even with the hand left open, so the entire body of the bird may be examined easily. In placing a band, the bird is preferably held on his back, with the little finger snugly over the throat, so that the thumb and first finger are in position to hold the leg while the band is adjusted. A record is kept of the family and species of each bird that is banded so that subsequently this information and his serial number may serve to identify him each subsequent occasion when he visits the feeding station."

The American Bird Banding Association aggregated 350 members, some of whom were expert ornithologists, although the majority were bird lovers and opera glass students without scientific training. During its existence its members banded between 18,000 and 19,000 birds and of this number approximately 375 were subsequently recovered. The mortality in bird life is very heavy and this is largely explanatory of why the recoveries on the part of the average bird student are only two or three per cent of the total number of birds which he catches and bands. Previously, systematic trapping has not been practised as efficiently as it could have been. The experts of U. S. Biological Survey hope to extend the potential recovery record to about ten per cent of the birds which are banded.



*Left:* For examination, the bird is usually held sitting upright, resting with his claws on the little finger and his neck between the first and second fingers. *Right:* In placing a band, the bird is held on his back, with the little finger snugly over the throat so that the thumb and index finger can hold the leg as the band is adjusted

**How migratory birds are examined and how they are labelled by means of leg bands**

In extending its investigations the Biological Survey is extremely anxious to get in touch with all bird lovers in the United States, especially with those who would be interested in coöperating with Uncle Sam in his bird study experiments. All those who now feed birds regularly can assist greatly in this campaign for increased knowledge about the birds by corresponding with Biological Survey, Washington, D. C., in order to be enrolled on the official list of feeding stations and to be provided with government bands and records for keeping track of the birds. At this time, lack of funds prohibits Uncle Sam from furnishing his layman field forces with traps. However he will supply simple plans and specifications so that any tinsmith can construct one of these traps without difficulty. If the bird lover prefers to purchase the trap on the market, it can be secured at a moderate price from Mr. J. Warren Jacobs of Waynesboro, Pennsylvania.

There are three distinct highways of land bird migration in this country where volunteer students can perform effective work. The first line of flight is along the Mississippi River Valley while the other two, respectively, are along the Atlantic and Pacific coasts. It is particularly noteworthy that during the migrations the birds do not make regular flights every day. They stop for some days in sections where the food is abundant and usually will resume their journeys

(*Continued on page 536*)

## How Meadow Mice Destroy Trees

**By William A. Murrill, Ph. D.**

ONE day early in March, I saw about noon at the elevated approach a brown rat, a gray squirrel, and a cottontail rabbit. The first two were actively hunting for something to eat, while the rabbit sat on the snow with its eyes to the sun fast asleep.

The brown rat is always with us, and is not only very destructive but helps to spread many diseases. The gray squirrel continues to be the delight of park visitors in spite of its shiftless habits, its fondness for buds and maple sap, and the fact that it destroys birds' eggs and young birds before they are able to fly. Two specimens of the black variety are frequently seen in the hemlock grove. The cottontail rabbits are fairly abundant in our grounds, making their nests near the buildings and being quite socially inclined. Although destructive in many sections, the injury done by them here is so slight as to be negligible. They seem to stand on top of the snow and reach for the young twigs, which they nip off with a clean cut. I do not know of a single case of girdling which can be attributed to them.

But the common meadow mouse is very destructive every winter, and he was unusually so during the one of 1919-20, doubtless owing to the abundance of snow and ice.

Walk through any grassy meadow and you will notice little runways forming a network over the surface of the soil and winding in and out among the vegetation. These are made by mice about as long as the common house mouse but with thicker body and shorter legs and tail. They keep the runways very smooth and free from straws so as to reach their burrows quickly in case of alarm.

In their comfortable nests of dry grass, several litters of from four to eleven young are reared each year. Hawks, owls, crows, foxes, weasels, and other natural enemies prey upon them continually—and still they increase. They consume large quantities of growing and matured crops and often destroy entire orchards by gnawing the bark from the base of the trunks and roots of trees. In winter they tunnel under the snow from one tree or shrub to another.

**The common meadow mouse, and a young apple tree showing a sample of his destructive work**

No store of food is laid up for cold weather by the southern species, but there is one in Alaska that gathers and hides in its nests a quart or more of little bulbous grass roots, which the Eskimo women search for eagerly and boil to serve to their guests during winter festivals.

To recount all the damage done by meadow mice in their search for food on our grounds during the past winter would make quite a story. A great many different kinds of trees and shrubs were attacked; and the attack was made in different ways according to the quality of the bark, the depth of the snow, the amount of dry grass present, etc.

The object of the mice being to get at the food stored in the inner bark, it was necessary for them first to gnaw away the outer corky layers, after which the tender inner layers were consumed down to the wood. On account of this complete girdling no food can pass to the roots, which will be speedily starved out and the trees will die. In the case of shrubs new shoots will spring up, but this will take some time.

Several of the splendid Japanese flowering cherries were completely girdled for a distance of six inches or a foot near the base. Four of these are young trees, six inches in diameter, and good bloomers; while one belongs to the first lot set out many years ago. Two other fine trees in the cherry orchard are nearly girdled and will either die or become practically worthless.

# The Service of the Chemist

*A Department Devoted to Progress in the Field of Applied Chemistry*

Conducted by H. E. HOWE, Chemical Engineer

## Research in Laundering

INTEREST is being aroused in Great Britain to undertake industrial scientific research in the laundry industry, and as an example of what may be accomplished reference is made to the research work conducted at the Mellon Institute, upon a Fellowship founded by the Laundry Owners National Association. Some of the problems awaiting solution are the economical use of heat and steam power, improvements in the construction and design of washing machines to reduce the mechanical wear on goods to a minimum, and a fundamental study upon the mechanical side of laundry practice involving such factors as time, temperature, and concentration. Then there is the influence of the ironing temperature upon the wear and tear of goods, and research upon the relation of design and weave of fabrics to laundry wear in order that we may choose the fabrics best suited to withstand this wear for those articles, such as collars, which require frequent laundering. The properties and most efficient uses of starch and the removal of old starch are other important fields. The removal of stains and scorch are further problems.

The results of research of this character would not only be of economical value, but would assist us in placing responsibility where it belongs, whether manufacturer, purchaser, or laundry man.

## Clay Soap

IN the January issue of *Chemical Age* (London) Mr. F. E. Weston discusses the utilization of colloidal clay in soaps. According to this writer the concentration of soap on the surface of the adsorbing bodies is the first factor in the detergent action of soap. Soap in water lowers the surface tension of water against air, and clay can be rendered so highly colloidal that it will display the same physical behavior in lowering the surface tension of a liquid in which it is in solution. Therefore, when such clay is properly mixed with soap it increases the detergent properties of it. In fact, it is reported that clay lowers the surface tension of water to an even greater extent than does soap itself, and experiments conducted with high grade soap with and without colloidal clay have verified this assertion. The commercial importance of this work will be in the replacement of a part, at least, of the fatty acids now used in soaps.

## Standardization of Glue

THE present standards by which glues are marketed are arbitrary and unfortunately not based upon scientific data. In the *Journal of Industrial and Engineering Chemistry* for April, George Hopp presents a new method for determining the tensile strength of glue which appears to give the exact strength and stretch of the material, its elastic limit, and other physical properties. Such a test will permit manufacturers to vary their processes and raw materials, determine the effect on the finished product, and permit the establishment of a standard which can be expressed in absolute units determined by scientific methods.

The method consists in melting the glue, pouring it into molds, and obtaining the stretch and strength of the sample on a tensile-strength machine, using cut strips of definite size. The article gives results of the work and outlines at least eight problems now under study to determine the effect of the variation of different factors upon glue.

## The Metallurgy of Tungsten

DR. C. W. BALKE has recently addressed scientific meetings on the metallurgy of tungsten, accompanying his presentation with various samples of this important element which but a short time ago presented what was then one of the most difficult technical problems. It will be recalled that this problem was that of producing ductile tungsten for use in incandescent lamp filaments and that success in this project is largely responsible for the efficiency of modern illumination. Today an equally important use of the element is in the manufacture of high-speed tool steel, in which utilization more impure material can be used than for filaments. The production of powdered metal from the ore is comparatively simple. This material is then pressed into ingots in hydraulic presses developing 250 tons per square inch. These ingots are then heated in an atmosphere of hydrogen to about 3,300 degrees Centigrade, which is just below the melting point, 3,350 degrees, tungsten having the highest melting point of any known metal. This sintering operation is controlled to produce a desired grain size in the mass. The mechanical work in producing pure tungsten wire is complex, and involves heating the ingots in special furnaces in an atmosphere of hydrogen and swaging the heated bars down to required size. The metal is passed through the swaging machine a great many times, as no more than 10/1000 of an inch reduction is accomplished each time. Eventually a size of 30/1000 of an inch is reached, after which the wire is drawn through steel dies until it is 20/1000 of an inch in diameter. Diamond dies heated to redness are now used until 15/1000 of an inch is obtained.

The manufacture of tungsten and its products requires very careful technique using hydrogen under dangerous conditions. It affords an excellent example of the development possible through chemical engineering, involving mechanical and electrical problems as well.

## Isolation of Vitamines

IT seems certain that the study of vitamines will influence our work upon foods to as great an extent in the next twenty years as has sterilization during the past generation. Isolation of vitamines is a particularly important study for there are a number of cases where cheaper foods could be made entirely satisfactory if we knew of some way to add, concentrated, the particular vitamine which it lacks.

In the proceedings of the National Academy of Sciences experiments upon the chemical isolation of vitamines are reported by Myers and Voegtlin. Working upon brewers's yeast, which is very rich in antineuretic vitamine, it was found that olive oil and oleic acid will remove the vitamine from the autolyzed yeast filtrate. The active material is readily extracted from dried yeast with acid methyl alcohol. The physiological action of the active fractions resembles that of extracts from the mucosa of the small intestine when the two extracts are purified in like manner.

## American Potash

FOR several years experiments have been conducted working toward the production of potash from the green sands of New Jersey. These sands are to be found in large quantities and contain about 7 or 8 per cent of potash. The Eastern Potash Corporation of New York is now constructing a plant designed to produce a thousand tons of potassium oxide annually. With this there will be residue estimated at 600,000 tons, which will be employed in manufacturing a silica lime type of brick. For this purpose the largest lime plant in the world is to be erected in conjunction with the potash plant. The equipment of the lime plant will consist of ten 8 x 125 feet rotary kilns producing a thousand tons of lime a day. The brick plant will have a capacity of 500,000 brick per day and this can be doubled if the demand justifies it. The project of winning potash from the green sands of New Jersey has been under consideration long enough to indicate that a sound foundation has been developed for this enterprise and the outcome will be watched with interest.

## Glycerine from Sugar

IN a recent issue of *Chemical Age* are to be found quotations from certain German technical papers to indicate that glycerine was produced upon a large scale from sugar in Germany beginning in 1915. Early in the war Germany had a considerable excess of sugar and the population was urged to use plenty of sugar on account of its food value. Later, however, on account of various uses found for sugar it became scarce and people found it difficult to follow the advice given earlier. The transformation of sugar into glycerine was accomplished by a biochemical method. It was known that with yeast, fermentation of sugar could be carried on in a way to convert 3 per cent of the sugar to glycerine; by the addition of various alkalies this percentage could be increased, and sodium sulfite was found to be the best material. As much as 36 per cent of the sugar was converted into glycerine. Acetaldehyde was also produced and was used for war purposes. The production of glycerine by this method exceeded 2,200,000 pounds a month and is a striking sample of the possibilities in the new fields opened through biochemical processes.

## Textile Misbranding

THE Federal Trade Commission recently ruled that seventeen concerns engaged in the manufacture and sale of underwear, shirts, and other wearing apparel must refrain from certain unfair methods of competition in commerce. The Commission's ruling made by agreement with the trade calls for more accurate branding of woolen goods and the firms named agree to refrain from using such brands as wool process, Scotch wool, Saxony wool, merino, or other descriptive brand to describe material not composed wholly of wool, unless the term describing the stock is coupled with the name of the other staples present in the fabric as, for example, worsted and cotton, or wool and cotton.

This is among the few rulings which have been made in the interest of textile branding. There are ordinances in several cities which if enforced would operate against the use of misinformation in advertisements, but these ordinances are seldom enforced. There is, however, one instance where the chemical laboratory was called upon to ascertain whether goods advertised by a merchant temporarily sojourning in a city conformed to the placards. The result was that the merchant moved on to other fields. The administration of laws designed to uphold recognized textile standards is difficult, but the time is certainly approaching when some way will be found.

## Concrete Tanks for Water Storage

TESTS on concrete tanks for water storage have been under way at the Bureau of Standards, where concrete of a mixture 1:2:4 were employed. After 150 days the day loss curves became a straight line indicating that the daily loss had become constant, and while the tanks showed some actual loss due to the penetration of the concrete by water they remained perfectly dry on the exterior. The head of water was 35 feet, but from the facts cited it would seem that this mixture when properly placed is waterproof to a satisfactory degree.

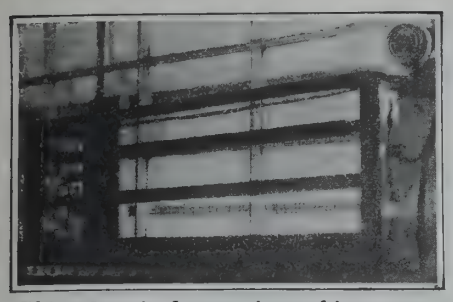
## Colloidal Fuel

NOTATION has previously been made in these columns of work done upon colloidal fuels by a number of chemists and chemical engineers. Since the processes devised under pressure of war emergency are applicable to various types of wastes, it would seem that colloidal fuels are sure to play an important rôle in the near future. If, as is claimed, such coal waste as culm, screenings, and dust can be used as well as peat, lignite, and sawdust, such a compounded fuel is indeed of unusual importance. Colloidal fuels are a combination of such fuels, particles of which are reduced to a size to make them colloidal, held in emulsion form by soap-like substances. When dispersed in fuel oil, tars, etc., can be held in suspense with sufficient permanence to permit storing, piping, and burning the mixture with the same facility as fuel oil itself. The subject is discussed by Jerome Alexander in the *Journal of Industrial Engineering Chemistry.*

## Water in Milk

A METHOD for detecting added water in milk has been devised by Dr. Hortvet of the Minnesota State Dairy and Food Commission. It is based on the constancy of the freezing point depression of milk observed by Beckmann in 1894. Milk has a constant freezing point due to a definite and constant relationship between the osmotic pressure of the blood and that of the secreted milk. Now, normal blood is constant in its osmotic pressure and milk must, therefore, also be constant. The freezing point of normal milk is its most constant factor, and while the osmotic pressure of milk would vary from the normal in under-nourished or diseased cows the marketed fluid is a mixture which is quite constant in this respect. It is not affected by the variable fat content nor the protein content and is the same for the first as for the last milk drawn, as well as for skimmed milk, separated cream, and the whole milk. The cryoscopic method distinguished between a normal milk of high water content and an artificially watered product.

The constancy of the freezing point has been established by many thousands of tests and the limits of depression have been found to be 0.54 degrees C. to 0.56 degrees C. The method has been found satisfactory to a minimum of 3 per cent of added water.



**This electric heater is nothing more than an old bed spring mounted on a wall**

## From Bed Spring to Electric Heater

IN its crudest form an electric heater is little more than a mass of iron wire which heats up as electric current is passed through it. This thought must have made a deep impression on a certain youth of Glenn Falls, N. Y., who rigged up an old bed spring in the manner shown in the accompanying illustration, for the purpose of heating his room.

Current from a pair of 110-volt wires is passed through the entire bed spring, causing the iron wires to heat up. Obviously, such an improvised heater is by no means the last word in electrical efficiency, but as an ingenious makeshift it is really commendable. No data is available as to the current consumption of this unique electric heater, but it must run up into several kilowatts if an entire bed spring is utilized and the heat obtained is considerable. And as to whether it is efficient or not, depends largely upon who pays the electric bill!

## Putting Runners on the Arctic Lifeboat

WHEN the British ice-breaker "Sviatogor" left Rosyth, Scotland, bound for some point in the Kara Sea where a number of Russian men, women and children were ice-bound on board the steamer "Solovie," she had many of the earmarks of the usual polar expedition equipment. Among other things were the lifeboats equipped with double runners, one of which is shown in the accompanying illustration. These lifeboats serve in a dual capacity, namely, as lifeboats in the water and as roomy, if somewhat awkward, sleds over the ice-covered waters.

The "Sviatogor" is one of the two most powerful ice-breakers in the world. She was sent to the rescue of the "Solovie" in response to the wireless calls of distress.

## Music Lessons for the Canary

AN enterprising young woman has recently established a conservatory of music where canaries are taught how to sing sweetly. A corner of this odd establishment is presented in the accompanying view, showing the feathered pupils, the director, and an ingenious compressed air apparatus which produces the desired music for the birds.

Briefly, the singing course is simply a matter of blowing different whistles which the birds mimic more or less faithfully according to their training. These whistles are mounted at the top of the cylinder in the center of our picture, in a metal box which is provided with a hinged door. The top cylinder telescopes with the bottom cylinder, so as to form a pump. The top cylinder is raised by means of a counter-weighted cable and allowed slowly to settle down into the larger or lower cylinder . The air compressed in the cylinders is permitted to escape through one or more whistles, thus producing the desired sounds for training the birds in the nearby cages.

## Paper, Paste and Ingenuity

WHILE we have been reading and hearing of the marvelous paper goods produced by Germans and Austrians ever since they became isolated during the World War, our own paper industry has been forging ahead along highly interesting lines.

Never before has there been such extensive use made of paper in one form or another. Certain manufacturers are turning out all kinds of paper goods from which numerous novelties can be produced. For decorative purposes certain manufacturers are producing so-called fire-proof crepe paper, which is a paper treated so as to burn quite slowly, removing the usual hazard connected with the use of paper. Papers finished to represent various kinds of wood are now used in making small frames.

The accompanying illustration represents a typical application of paper products. Here shown is a lady's hat made entirely of crepe paper, cardboard for the shape, and a few flowers or fruit of paper for the trimmings. True, such a hat is a short-lived novelty and will not stand rain; but is it any different with the usual lady's hat?

## New Coal Fields in Spitzbergen

THE director of the Swedish coal fields in Spitzbergen, Mr. Granholm, who has just returned to Stockholm, confirms the statement recently published in a local paper regarding newly discovered coal deposits on that island. It appears that these have been found at a depth of 26 feet below what has heretofore been considered as the bottom of the "Svea Mine." The vein recently opened, according to the director, has an average thickness of over 6 feet, with an estimated area of about 16,000,000 square feet. Up to the present none but expert miners have been employed at the "Svea Mine" in Spitzbergen, because of the difficulty in working the old 80-centimeter vein, but in the new vein unskilled labor may be utilized.

During the present year the output is expected to be 36,000 tons against 18,000 tons in 1919, while in 1921 the director estimates that at least 72,000 tons will be ready for shipment.

## A Fountain in a Bottle

A VERY curious little experiment may be carried out with a few simple materials. First of all fill a four-ounce bottle three-quarters full of water. Pierce the cork and insert a glass tube of small diameter. This tube must be long enough nearly to reach to the bottom of the bottle and project a little above the cork. Seal the cork airtight with sealing wax.

Now fold several sheets of wet blotting paper and stand the bottle on this. Next, get a large glass jar and hold this upside down over a lamp or a candle flame so that the air is well warmed. Then, still in an inverted position, press the jar over the bottle taking care that the edges are in close contact with the blotting paper so that the outer air is excluded.

In a few minutes the contraction of the air in the jar as it cools will cause a jet of water to rise up from the bottle. This will reach almost to the top of the jar and will be like a miniature fountain. If the glass tube is slender, so that only a little water passes at a time, the fountain will last quite a long while.

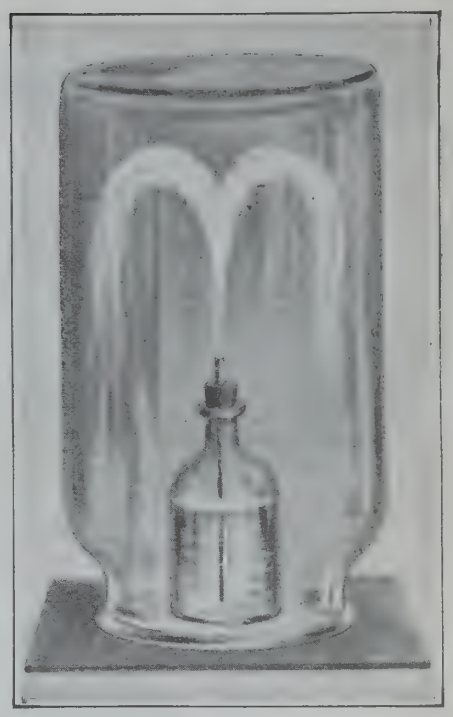
**This paper hat costs 25 cents and lasts long enough to serve its purpose**

## The Vertical Camera and Its Uses

FOR the photographing of machinery parts, jewelry, books and other loose objects, the vertical camera is employed in most of the leading commercial studios. Such a camera forms the cover subject of this issue.

The vertical camera can be racked up or down so as to secure an image of any desired size; and the focusing is accomplished by racking the rear end of the camera up or down until a sharp image appears on the ground glass. Where small objects are to be photographed and absolute sharpness is necessary, it is not unusual for the photographer to make use of a ground glass sheet under the subjects. A light coming up through the ground glass on which the subjects rest facilitates the work of focusing the camera.



**A fountain produced in a bottle by simple means**

## Thawing Frozen Water Pipes by Electricity

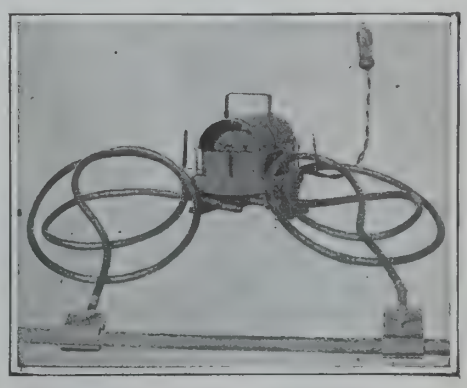
ONE of the latest developments in electrical convenience is the electric pipe thawer. Its function is to thaw frozen water pipes in a house electrically, a method which has considerable advantages over using a gasoline blow torch, or other ways attended by more or less fire hazard and inconvenience.

The device consists of a small transformer which can be connected to the house lighting circuit by means of a 10-foot lead and separable attachment plug which are provided. The two secondary cables, or those which are attached to the pipe to be thawed, are each seven and a half feet long and end in a cast brass clamp which can be used on pipes varying in diameter from one-half to one inch.

The purpose of the transformer is to reduce the lighting voltage to a point where a sufficient heat will be produced to thaw the pipes. This heat is produced by the resistance of the pipe itself to the flow of the current, and only about the same amount of energy is used as in running an electric flat iron.

In thawing out a pipe the nearest faucet should be turned on, and the secondary leads of the transformer connected to the pipe at a point nearest the entrance of the pipes from the street, the pipe being heated in sections until the water flows out of the faucet. The time required to thaw out a pipe depends on how long the frozen section is, the size of the pipe, and the degree to which it is frozen.

The whole apparatus is very compactly made, and easily portable, having a handle welded to the transformer case and weighing only 35 pounds complete.



**This electric thawing device thaws out frozen pipes in sections**

# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*

**This truck is a sprinkler in summer, an enclosed ash and garbage collector in winter**

## Double Service Municipal Truck

THE advantages of motor trucks for municipal use have been previously considered in these columns and many interesting examples of trucks have been illustrated. One of the drawbacks to the use of specialized equipment has been that in some cases it could not be profitably employed all of the year round. The accompanying illustration shows a double-service truck equipped with special bodies that are easily removed so that the same chassis can be employed for a number of distinct body types. For example, for summer service these chassis are fitted with large capacity tanks equipped with flusher and sprinkler attachments. During the winter season, when watering the streets would make traffic hazardous, even though it was thought necessary, the same chassis are converted into automatic dump trucks with enclosed steel sanitary garbage and ash-collection bodies.

At a time when increased facilities are needed for removing ashes, due to the universal use of heating equipment that is idle during the summer, the added motor equipment necessary is obtained by mounting relatively inexpensive bodies on the more costly chassis, which would otherwise remain idle if the design did not include the convertible feature. It was formerly necessary to lay up flushers and sprinklers during the winter months, this representing a considerable loss on the truck investment. The advantages of trucks adapted for the quick interchange of body equipment are apparent and attachment of special municipal adjuncts make an all-the-year truck investment. The machine illustrated is one of a large fleet of similar designs, used by the New York Street Cleaning Department.

## Trailers Reduce Cost

SLOWING down of business conditions and curtailment of credit in many lines have not affected the trailer industry much, according to reports of members of the Trailer Manufacturers' Association. There have been few cancellations and these have been offset by increased orders. The trailer people expect that as general business gets down to a more economical basis, manufacturers and merchants will look more closely to the cost of transportation and will adopt the trailer more generally as a sure means of reducing the cost of haulage and delivery. The increase in railroad freight rates is confidently expected to result in a larger development of the ship-by-truck movement. Shippers have already found that goods can be shipped more cheaply and quickly by motor truck than by rail for distances of fifty miles or more, and with an increase of 20 per cent in rail rates, there will be a still greater inducement to patronize the highway lines. The reason for the popularity of the tractor and trailer for nearly all hauling purposes can be very well understood by referring to the accompanying illustration which presents in a graphical manner the argument advanced by those favoring the use of trailers.

**A maker of automobile parts uses this trailer in his delivery to advantage**

## Trucks in Imperial Valley

THAT motor trucks are called upon to work under the most adverse conditions, but are meeting those conditions in a manner characteristic of an engineering achievement, is shown by fifteen motor trucks operating in the Imperial Valley, California, which is 119 feet below sea level with roads built of silt deposits from the Colorado River. It is situated about half way between Los Angeles and San Diego, and has a total population of 60,000 people who last year produced $66,000,000 worth of products. The water is all brought in by canals from the Colorado River. On account of the soil being silt, the roads are very bad and extremely dusty. It is the opinion of people living in California that there is no place in the United States where a motor truck is put through such unusual tests as in the valley.

During the summer months the temperature very seldom goes under 100 degrees a day or night and during the daytime the thermometer reaches from 130 to 135 degrees in the sun. For many months this fleet of fifteen motor trucks has been operating continually without interruption in the Imperial Valley hauling cantaloupes, watermelons, etc., from the fields to the packing pits and to the refrigerator cars under the most adverse conditions, not only in temperature, but in contending with traction difficulties due to the soft fields and sandy silt, hub deep, piling up in front of the wheels. An instance that shows climatic extremes with which these machines must contend is that of a 2½-ton power wagon loaded with watermelons weighing 8,500 pounds, starting from the valley 119 feet below sea level, making 70 miles of mountain grades after dark, reaching an altitude of 1,420 feet and then down to sea level again at San Diego.

## Truck Saves Money in Road Building

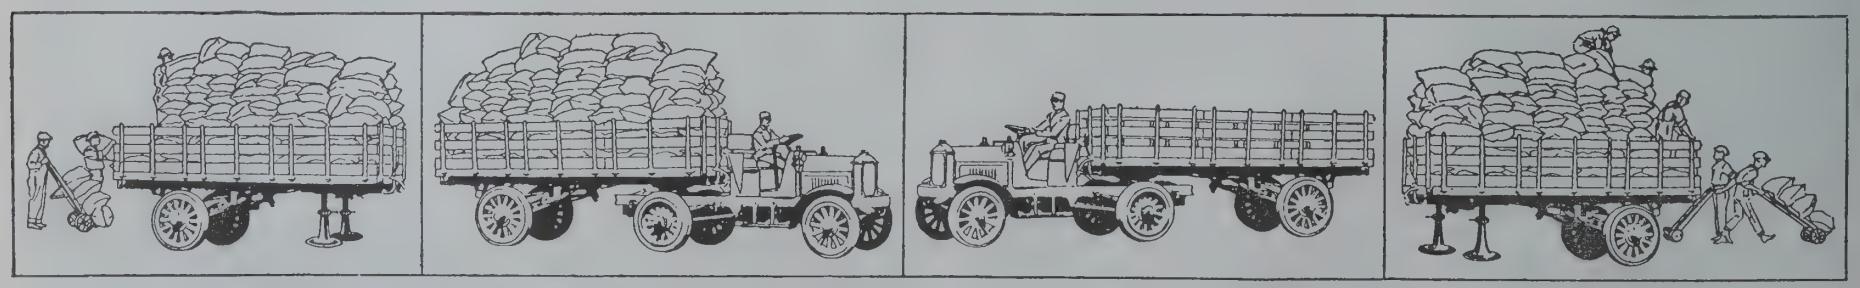
A THREE-AND-ONE-HALF-TON motor truck, equipped with a combination dump body, is doing state road work at Belgium, Wisconsin. It is said that this truck took the place of seven teams and saved the owner $33.25 per day. This road contractor, while doing State work, recently made some very interesting discoveries regarding the motor truck in road building. He was employing seven teams and fourteen men at the time the three-and-one-half-ton truck was received and set to work. The seven teams had each hauled three loads per day of one and one-half yards each, a total of thirty-one and one-half yards per day. By truck two men hauled thirty-three yards of crushed stone each day. Figuring the cost of each team and driver at $7.25 per day, the contractor was paying $50.75 per day for his seven teams. Assuming $17.50 per day for one motor truck, it will be seen that the motor truck saved him $33.25 per day.

It has been proved times without number that the motor truck will do as much work as six to eight horses and is much more economical to maintain and some users claim almost double that figure, the cost per day to operate four teams being in one case $29 and the cost per day to operate one truck $17.50. Here is a distinct saving of a trifle over forty per cent, and that is not all by any means.

**Motor truck with interchangeable dump and stake-bodies, used effectively on road work**

The all-steel dump body used was equipped with a special hoist. On two-ton bodies, 12-gage steel is used and on three-and-one-half and four-ton bodies 10-gage steel, while on all bodies the front end and tail gate are made of 8-gage steel. To preserve proper balance in dumping, all wide bodies of three and one-half tons have a special design worked out in the hook-up of the hoist to the body, which provides a front bearing for lifting of forty inches between centers. Consequently, an uneven load does not throw the cross strain into the body as does the usual narrow hook-up. For rock, sand and gravel, the four-and-one-half-ton truck has a length of 132 inches and a total width over the flare of 81 inches, the height being 16 inches, with a capacity of three and one-half cubic yards and a weight of nine thousand pounds.

The combination dump and stake body is sometimes used to combine the advantages of the all-steel dump body with those of the stake body, having dump- and stake-body sides interchangeable. The dump-body sides, and the stationary battlements which support the lifting arms, are constructed of rolled steel, reinforced with angles. The battlements, 24 inches high and 30 inches long, unite with the dump-body sides in forming an inside body compartment that can be dumped absolutely clean in twenty seconds. The tail gate for use with the steel body sides has its opening regulated to permit gravel, crushed rock, or other materials to be spread by the truck as it moves along. When not in use as a dump body, the steel sides and steel tail gate are instantly removable and side stake gates 36 inches high are substituted in their place, and a stake-body tail gate which hinges at bottom placed in position. A 10-inch and 14-inch wood reinforced tail gate, when lowered, extends platform length to a practical 10-, 12- and 13-foot stake body in the two-, three-and-one-half and four-tonners, respectively. The sub-frame is built of rolled steel channel and the floors are covered with 14-pound steel plates, fastened with bolts. The four-ton truck body for rock, sand and gravel has a length of 132 inches and a width of 80 inches, the height being 15 inches.



While one trailer (extreme left) is being loaded, the tractor is hauling a loaded trailer (left center) or returning with an empty trailer (right center), while all the time another trailer is being unloaded (extreme right) at the other end of the run

## Of Interest to Farmers

GOPHER TRAP.—J. F. STANKIEWICZ, Bandon, Ore. An object of the invention is to provide an animal trap more especially for catching gophers, moles and other burrowing rodents. Another object is to provide a light metal trap which is strong in construction and which may catch two animals simultaneously, and that may catch the animal going into or out of the burrow.

TRACTOR.—E. E. LARSON, 651 S. Park Ave., Mason City, Iowa. The invention relates to tractors characterized by propelling members of the walking type. The tractor compresses rolling means supporting one end of the frame, endless tracks associate with the other end of the frame, a carriage on each of the tracks, a shoe associated with each of the carriages, and means associated with the shoe for accelerating the movement of the carriage when the shoe is moved from inoperative to operative position.

## Of General Interest

UMBRELLA AND PARASOL.—I. H. WEINBERG and C. F. BISBING, 23 E. 21st St., New York, N. Y. An object of the invention is to provide an attachment which operates to hold the ribs of the umbrella or parasol close to the handle and which also provides a convenient means for supporting the umbrella on the wrist or arm of the user. A further object is to provide an attachment which can be conveniently located on any ordinary umbrella or parasol and which will also be ornamental and attractive.

DATE STAMP LOCK.—A. MILLER, 70 Greenwood Ave., East Orange, N. J. Among the objects of the invention is to provide means for use in connection with conventional and standard type dating stamps for locking the type in alined printing position. It is also an object to provide a device which may be mounted upon the available space of the base plate of ordinary dating stamps, and which will compressibly engage the several type-carrying belts.

WEATHER STRIP.—C. J. JONES, 1319 Champa St., Denver, Colo. This invention has for its object to provide a weather strip for the meeting edges of window sash and frame, the meeting rails of the sash or the meeting faces of the door frame and door, which serve to keep out air and which form a snug juncture of the parts to prevent rattling. The device may be readily attached without skilled labor.

COLLAPSIBLE TUBE.—E. L. CLEVELAND, 941 Ainsworth Ave., Tacoma, Wash. The invention has reference more particularly to that class of tubes which are adapted to contain tooth paste and other plastic or semi-plastic materials and from which the contents are discharged by distorting the tube. The primary object is to provide means whereby a given quantity of the contents may be expelled without having the discharge continue after the pressure has been relieved.

COMPOUND CRAWLER.—E. RIMAILHO, 12 Rue de la Rochefoucauld, Paris, France. The object of this invention is to provide a compound crawler tractor with steerable propelling means which is particularly useful with gun carriages of heavy artillery, and for transporting and firing ordnance as well as for transporting loads of any kind, since it provides means for moving them on varying ground, while still allowing their travel on the road by their usual means.

BRUSH HANGER AND PAD REMOVER.—M. P. BENSON and M. M. WIENER, Monarch Brush Co., Troy, N. Y. Among the objects of the invention is to provide a hair brush comprising a rigid back with integral handle and a flexible removable pad carrying the bristles, the pad being removable for the purpose of cleansing, or other purposes, the specific object being to provide a means for ejecting the pad from the brush back.

CLAMP.—S. R. LIBBEY, Brady, Mont. The invention has for its object to provide a clamp especially adapted for use in connection with tubs to clamp a cover of flexible material over the tub without the use of nails, staples or the like. In practice a corrugated wire is used for providing resiliency in the event of expansion and contraction; the clamp is adapted to receive a seal.

DISPLAY STAND.—J. M. WALTERS, c/o J. W. Robinson Co., 7th and Grand Ave., Los Angeles, Cal. Among the objects of this invention is to provide a form of stand adapted for the display of evening gowns and lingerie, underwear and the like, wherein the fixture is so constructed that it will be hidden by the garment displayed. A series of attachments for each class of article to be displayed is provided for connection with the stand.

CAMERA.—C. G. JOHNSON, Eau Claire, Wis. The object of the invention is to provide mechanism in connection with folding cameras for permitting an exposure to be made on a lesser portion of the film than is usually exposed, provision being made for varying the size of the film desired for exposure, or permitting a picture to be taken the full size for which the camera was originally intended.

ALLOY.—V. P. TAYLOR, address 2.A. Dr. Bilisano, Dominguez, 42 Mexico D.4. Mexico. This invention relates to a metal compound, and aims to provide a product which will combine practically the lightness of aluminum with the strength of extremely hard metals. The alloy contains aluminum 80 to 100 parts, copper 8 to 17 parts. After the mixture has been melted small quantities of sodium tungstate, potassium, bichromate, and finely granulated cast iron are added.

DETACHABLE TOOTH.—C. A. CONOVER, Newburgh, N. Y. The invention relates particularly to a removable tooth, and has for an object to provide a construciton which will be mechanically effective for the purpose desired, and at the same time a construction which will present a pleasing appearance. The construction is capable of application to a bridge or crown, and may be applied at any time on the upper or lower jaw.

APPARATUS FOR EXTRACTING RESIN AND ALLIED PRODUCTS.—W. EDENBORN, c/o La. Railway & Navigation Co., 520 Hibernia Bank Bldg., New Orleans, La. Among the principal objects of the invention are to avoid retreatment of wood particles for the separation of resin previously extracted therefrom, to reduce the cost and simplify the method of extracting resin from wood particles, and to reduce the time factor for the extraction.

## Hardware and Tools

TOOL FOR ALINING AND FITTING MACHINE PARTS.—J. PEYER, 634 2nd St., Brooklyn, N. Y. Among the principal objects of the invention is to remove the necessity for performing the work for which the tool is designed under cramped or inverted positions, to insure greater accuracy in the work performed, and to correlate the various operations incident to alining and fitting machine parts. A broad purpose is to provide a tool to be used for fitting and realining the wrist pin bearings and connecting rod bearings in automobile engines.

DOOR LOCK.—E. E. L. MONTELIUS, 113 E. 75th St., New York, N. Y. This invention pertains more particularly to a door lock used in connection with a dumb-waiter shaft, which will render such doors incapable of being opened unless operated by a person in charge who would be in the basement of the building. A further object of the invention is to provide means associated with the lock which will prevent the unlocking of any doors other than those to the rear of which the dumb-waiter is positioned.

BUTTING TOOL.—R. W. AYLING, 427 17th St., West New York, N. J. The invention relates to tools used in temporarily bolting sheet-plates together, and has for an object the provision of a construction wherein the tool will coact with a wedge for causing a temporary bolt to be properly positioned when acting as clamping means for holding two sheets of plate together. A further object is to provide a tool which may be held manually.

WINDOW SCREEN CATCH.—J. B. BRADLEY, Box 1230, Miami, Fla. The invention relates generally to window screens, and more particularly to window screens which are hingedly connected adjacent to their upper side portions to swing at their lower portions toward and away from the sub-sill of the window frame; the object is the provision of a simple inexpensive catch fastening capable of ready adjustment and ready installation as well as durability.

## Heating and Lighting

OIL BURNER.—W. B. BOOKER, Freeport, Texas. This invention relates more particularly to a burner designed primarily for burning crude fuel oil, an object being to provide a construction which insures the centering of the oil discharge spray head within the burner head. A further object is to provide means for submitting the oil to the temperature of steam before reaching the burner so as to vaporize the oil and insure a perfect mixture with the steam for burning.

GUARD FOR GAS STOVE COCKS.—J. LAYDON, 268 19th St., Brooklyn, N. Y. The general object of the invention is to provide an attachment to be applied to a gas stove to prevent the accidental opening of the gas cocks by a person brushing past the same or the striking of the handle of the cock by another object. A further object is to provide a device which is simple and may be readily adjusted to close and guard those cocks not in use yet permitting any selected cock to be opened.

OVEN GRILL.—G. B. CASWELL, address Wm. Calhoun, Ast. E. & R. Officer, Fort Terry, N. Y. The object of this invention is to provide a grill fitting into the oven and adapted to support one or more food containers and arranged to permit the user to readily raise the containers from normal lowermost position to any desired height in the oven without danger of spilling the food, shaking it or otherwise handling it to detriment of the food.

## Machines and Mechanical Devices

TEXTILE FABRIC TREATING MACHINE.—L. CLARENBACH, 159 Hamilton Ave., Passaic, N. J. The invention relates to machines for treating textile fabrics in the open width with liquid, and has for its principal object to provide a machine in which the liquid is caused to thoroughly penetrate the fabric as it passes there through in a minimum time and uniformly, the fabric being forced against the liquid.

OPTICAL PRINTER.—H. B. BYRON, 359 E. 155th St., New York, N. Y. This invention has particular reference to photographing machines having a fixed optical center. Among the objects is to provide a negative holder having a plurality of light apertures adapted to be brought in succession into the axis of the light with facility and optical precision, whereby a more rapid or more perfect adjustment may be effected than would ordinarily be possible.

OIL ABSORBING DEVICE.—A. E. ALLEN, 25 72nd St., Brooklyn, N. Y. The invention relates to an oil absorbing device adapted to engage the needle bar of sewing machines to absorb any excess of oil which may accumulate on the needle bar. The primary object is to provide a device which may be easily applied and manufactured at a modest cost.

COMPENSATING APPARATUS FOR WELL DIGGING OUTFITS.—O. E. OAKES, Baxter Springs, Kas. A specific object of the invention is to provide a frame with reciprocally mounted spring-held pulleys to which a wire line is applied and which is so employed in connection with the drilling outfit that the springs are made to take up shocks and unusual strains in the drill cable to prevent breakage thereof.

PUMP.—W. R. TWIFORD, Manville, Wyoming. Among the objects of the invention is to provide a pump that is easy to operate, the column of water in the delivery pipe being counterbalanced by the pump plunger in a different pipe, to provide a pump in which the working parts are subjected to the least amount of wear, and being so designed that sand or other solid particles that may pass upward from the well with the water will never come in contact with the working parts of the pump.

HANGER BLOCK.—P. A. FRIEL, 84 W. 6th St., Bayonne, N. J. This invention relates to mechanical connectors and has particular reference to means for attaching planks, beams, studding, or the like to concrete or composite girders, posts, walls, etc. Among the objects is to provide a connector or hanger block adapted to be secured or snubbed to the flange of an I-channel or T-beam during the construction of a composite building element such as a girder.

## Prime Movers and Their Accessories

PRESSURE REGULATOR.—L. LEBRAS, 219 W. 66th St., New York, N. Y. The invention relates more particularly to an automaitc controlling device for the pressure of air utilized in liquid fuel feeding devices, such as commonly employed for internal combustion engines in connection with aviation motors or other forms of motor-propelled vehicles. An object being to provide an apparatus which will insure the maintenance of a uniform pressure in the liquid fuel tank for feeding fuel to the carburetors.

INTERNAL COMBUSTION ENGINE.—G. B. GERAU, 1393 E. 82nd St., Cleveland, Ohio. An object of the invention is to provide a shuttle valve piston for an internal combustion engine, the arrangement being such that the necessary valve mechanism is embodied in the piston and operated from the crosshead of the connecting rod, thereby eliminating a considerable portion of the weight of the engine ordinarily represented by the cam shafts, lift rods, etc.

BREATHER FOR GAS ENGINES. — A. PAJALIC, Dearborn, Mich. An important object of the invention is to provide a breather, which will serve to allow free escape of compression from the crank case, and will serve to separate and return to the crank case any entrained oil or the like. Another object is to provide for the exclusion of dust or other foreign substances from the crank case and for allowing for the admission of air.

## Pertaining to Recreation

TOY AIRPLANE.—A. Z. BAKER, 301 Washington St., Newark, N. J. A general purpose of the invention is to provide a toy airplane of the knock-down or dismantled type in order that it may be packed for the market in comparatively small cartons to facilitate transportation and distribution. A further purpose is to provide a toy airplane assembling the wings, to eliminate the use of permanent structural means such as screws, nails or tacks.

## Pertaining to Vehicles

AUTOMOBILE BODY CONSTRUCTION.—J. J. JONES, 145 S. Hillside, Wichita, Kan. The invention relates more particularly to small light vehicles including four-wheeled frames, but which are known as cycle cars. This type of vehicle is distinguished for its minimum air resistance, its light weight, its low center of gravity increasing its tractive qualities, but is ordinarily limited to two passengers. The object of the invention is to provide a body construction which will permit of the seating of four passengers comfortably without great increase of weight.

LUBRICATING MEANS FOR LEAF SPRINGS.—H. RIGBY, 899 E. 19th St., Paterson, N. J. The object of the invention is to provide means for lubricating leaf springs of automobiles and other vehicles and devices arranged to permit the use of standard parts thereby reducing the cost of manufacture to a minimum and to permit convenient replacement of the parts, if necessary.

AUTOMOBILE LOCK.—J. W. HUNTER and E. WILLIAMSON, Mobile, Ala. An object of the invention is to provide a lock or holding device for automobiles, which will prevent turning movement of the steering wheel and which can be readily moved out of the way when not in locking position, and securely locked when in position to hold the wheel, and prevent steering by any one except the rightful owner.

TRANSMISSION CASE.—G. H. PADGETT, Pinecastle, Orange County, Fla. The aim of this invention is to provide a case construction in such manner that it will be possible for access to be had to the transmission without the destruction of the oil-proof gaskets and with which the entire operation may be completed by one man in a fraction of the time usually required by two; furthermore it is not necessary with this device for the operator to be under the car.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## Something Different in Salvaging Operations

(*Continued from page 518*)

lower end, designed to engage the bottom edge of the trunks and to discharge into the water surrounding these structures. In fact, the ease with which the crook-like pipes could be got into place from the surface and the certainty with which the air could then be controlled from the salvage craft made them the principal aid by which the buoyant medium was manipulated during the refloating of the "Canadian Recruit." It should be understood that the under-water plating of the hull abaft the engineroom was intact and necessitated no repairs in the region where compressed air was applied. Forward of the after bulkhead in the engineroom, however, divers had to patch the injured shell. With that done, the unwatering of that section of the steamer resolved itself into a simple job of pumping, for the deck and hatches throughout that stretch to the bow were above the surface of the river.

By reference to Fig. 3 it will be seen that the stern of the steamer rose to the surface when sufficient air had been forced into the cargo space; and it will be observed that the level of the water in the trunk coincided with that of the surface of the river. In Fig. 4, however, the moment before the vessel righted herself and ceased to rise higher, it will be noticed that the level of the water in the trunk was below that of the river and yet higher than the surface of the water generally in the hold. This plainly indicates the thrust of the confined air and the manner in which the movement of the column of water in the trunk served to relieve the bursting pressure of the compressed air. A few moments later the air was free to escape upward into the trunk, and the superposed water was blown into bubbles and spray like a sizzling bottle of soda.

This new salvage device, so simple in its get-up and comparatively easy to instal, furnishes at once a ready solution of many of the vexing questions involved in raising a deeply sunken ship by recourse to compressed air applied internally. Where the circumstances permit its employment it does away with the need of ordinary compensating apparatus, because each trunk becomes in effect a great automatic relief valve that can be depended upon to function correctly as the enveloping hydrostatic conditions alter. It was just the absence of any prompt and ample means for taking care of the expanding air, as the ship rose, which frustrated one of the initial stages of the refloating of the U. S. S. "Yankee."

Active work on the "Canadian Recruit" was started on the 16th of May of the present year, and she was floated clear of the shoals fifty days later, forty days of that interval having been taken up in removing cargo. Ten minutes after air was turned into the after hold her stern rose clear above the tide.

## A New Magnesium Alloy for Motor Pistons

(*Continued from page 519*)

Where this metal is re-worked or rolled, drawn, drop forged or heat treated, the tensile strength is increased at each operation. In heat treating, sand castings are increased from 22,000 up to 30,000 pounds, without causing any appreciable change in the yield point, while the elongation and reduction in area are increased 6 per cent. In drop forging, the tensile strength is increased to 50,000 pounds and the Brinell hardness rises to 70 or better.

The first real test of pistons of this metal was begun in a light roadster over a year ago. The car has been in constant service since that time; it now has a mileage of over 20,000 and is still giving good service. At one time on a 5,000 mile test, the gas consumption was 23¼ miles per gallon and the oil at the rate of one quart for each 100 miles. At the conclu-

*Superheat demands strong harness*

IT chisels its way past and through otherwise proven "steam" metals.

Only Monel metal has been able to hold superheat to its work for only Monel is immune to the peculiar chemical and abrasive action of high speed gases.

This natural alloy armors the toughness of copper with the well recognized rust, wear and corrosion resistance of nickel. Its coefficient of expansion is identical with steel, its strength is fully its equal.

So we find Monel metal made standard for vital parts by leading valve manufacturers. It has a prominent place in the specifications of engineering firms of the standing of J. G. White, Stone and Webster, Dwight Robinson Co., etc., where acid, alkali, high heat and steam wear resistance are called for.

THE
INTERNATIONAL NICKEL COMPANY
43 Exchange Place, New York
The International Nickel Company of Canada, Ltd., Toronto, Ontario

The name Monel is given to a line of metal products produced by The International Nickel Company from a natural nickel alloy —67% nickel, 28% copper and 5% other metals. These products include Monel blocks, Monel rods, Monel castings, Monel wire, Monel strip stock, Monel sheets, etc. The name Monel identifies the natural nickel alloy as produced by The International Nickel Company.

sion of the test, the piston showed very little wear and the cylinder none.

A recent test in a plant of a well-known manufacturer of motors showed that these motors developed six horse-power more with the new metal pistons than they had ever developed before with any other material. In spite of the rather ample clearances with which these pistons are installed in the cylinder, no case of oil pumping has yet been recorded and the objectionable piston slap is absent. The possible applications in the automobile and in airplanes are apparent to the automotive engineer.

## A Giant Ingot Mold Casting in the Making

(*Continued from page 519*)

Owing to the height of the casting, and the consequent high head of liquid metal, it can readily be seen that the pressure at the bottom of the mold would be a serious factor in pouring this casting; in fact, the pressure at the bottom would be so great that there would be a tendency to crush the core and force the walls of the mold inward, thereby reducing the diameter of the casting at this point. One of the problems, therefore, was to construct the core so that it would be sufficiently strong to withstand this crushing tendency and at the same time be sufficiently pliant so that it would yield to the shrinking process which takes place as the casting cools. It should be sufficiently porous to allow the escape of the gases that are generated in the core through contact with the heat of the molten metal. As the rate of shrinkage in the diameters at the bottom of the mold would be different from that at the top, it was, of course, necessary to regulate the diameters of the core and mold at the top and bottom to such a degree of nicety that when completely cooled and all shrinkage had ceased, the resultant diameters would be alike at both ends of the casting. One of the illustrations shows the special core being lowered into the mold in the ground. The weight of the finished casting was approximately 114 tons, but to pour it there was provided a total quantity of 135 tons, the excess representing gates, runners and the riser which was cast on the mold as mentioned. In order to have this large quantity of metal ready for pouring at one time, it was necessary to make special provision for storing a large portion of it. This was done by building adjacent to the mold a large reservoir with a capacity of 70 tons. This reservoir was made up of cast iron pigs and properly lined with fire brick and clay to hold the molten metal. In addition there were three ladles of molten metal holding respectively 25, 30 and 10 tons. The 70-ton reservoir was connected to the mold by means of a trough, and at the proper moment the plug at the bottom of the reservoir was withdrawn and the molten metal released and conveyed to the mold through the trough. At the same time the ladles were poured into the mold through other similar runners.

## Aircraft of the Future

(*Continued from page 520*)

small variations in altitude as are the planes of today, for the whole use of the air as a means of transportation means the use of all levels where life can be sustained, and the running of passenger and freight planes where they will meet the least resistance and consequently operate with the greatest economy.

The problem of the air-screw (propeller) receives a great deal of attention at the hands of the committee. They summarize the outstanding problem as one involving the construction of a screw with blades adjustable in pitch. The problem is twofold, involving (1) determination of its aerodynamic proportions and pitch so that under widely varying conditions of flight at varying altitudes, varying speeds and varying degrees of climbing, the screw may present always the most satisfactory curvatures to accomplish the desired end with the available power; and (2) the construction of such a screw.

The determination of the theoretical proportions is a problem well in hand. The making of such a propeller which shall properly function has not yet been achieved. So it is proper material for a prophecy to the effect that the airplane of the future will have adjustable propellers capable of combining with its variable wing-surface and camber to produce variations of speed, lift and revolution-per-minute, to the end that a plane be able to function most effectively at many speeds and altitudes with the minimum of power and weight.

The committee finds that the greatest problem of all is the "best economic utilization of the enormous investment which has been made in aeronautical production, expressed in terms of money and human time and energy."

Basing, then, the final prophecy upon the final problem, it seems inevitable to state that the plane of the future will have at least as great a part to play as steam transportation has had in the development of civilization. That the airplane will eventually make war impossible because too destructive of civilian life is the hope of those who see universal peace not as a vision but as a practical possibility. That the airplane will eliminate time and distance in a wholly new sense is already assured. That it can only do so commercially by being made entirely safe and wholly economic is obvious. That the path to these desired fields lie through the speedy solution of mechanical problems here outlined hardly needs demonstration—that this "prophecy" of what the plane of the future must be is based upon concrete facts and not at all upon fancy is its only excuse for being.

## Our Coal in the Making

(*Continued from page 522*)

ward speed of the tractor-like machine is such that enough raw material is excavated, macerated and dried to prepare from 5 to 10 tons of dry fuel for each working hour. The machine may be operated by gas or electric motor, but about 50 horse-power is required. One man operates the machine. The cost of peat fuel, so prepared, Mr. Garnett estimates at about $2.25 per ton at the swamp.

During the process of maceration a glue-like substance held in the plant cells is liberated and this acts as a cement for holding the briquets together and as a waterproofing agent. It will be noted that the raw peat is placed on the ground, which is, first, the easiest place to put it; and, second, has the advantage of keeping the under side of the bricks moist, permitting the moisture to be driven upward by contraction of the bricks. Bricks dried in racks often crack to pieces due to rapid surface drying. After the bricks are dried they are taken up by hand and then are run through a crusher and delivered to the consumer for hand firing, the same as crushed coke, the size being determined by local requirements.

A Minneapolis company has made extensive experiments in the preparation of a pulverized fuel from this peat and they have obtained surprising results in firing pulverized peat in competition with pulverized coal.

Tests recently run in a big office building in Minneapolis showed that the evaporation per pound of coal was only ten per cent higher than per pound of peat. This appears to contradict the fact that the B.t.u. value of the peat was only about two-thirds that of the coal. But credit is not given in the B.t.u. test for the fact that the peat contains very little carbon and burns with almost no ash, and in addition contains oxygen of its own, which the coal must obtain from the air. This latter is a very important consideration,

(*Continued on page 534*)

# Main Drive Insurance

Is your main drive insured against belt unreliability? Are you getting satisfactory performance from this all-important link in your chain of production?

A Rainbow Belt of the requisite weight for the work to be done is, we believe, the nearest approach to absolute reliability in belting performance.

Rainbow Friction Surface Belt is the result of the combined experience of all our mechanical rubber factories. It is a finished product of the finest materials put together with all the skill of the belt-maker's art.

Compared with a great many other fabric beltings, the initial cost of Rainbow is slightly higher. Its "service cost"—which affects profits—is reduced to the lowest point by absence of shut-downs for shortening and repairs.

The United States Rubber Company stakes its high reputation on Rainbow Belt and on the unqualified success it has won.

## Our Coal in the Making

*(Continued from page 532)*

for in obtaining oxygen from the air a very large amount of inert gases must be heated to combustion heat and these do no work. The peat is burned with the dampers almost closed, using only about one-half the air required to sustain combustion in the coal.

Burner equipment, it is claimed, for pulverized peat costs only about 80 per cent of the value of automatic stoker equipment, maintenance costs are about 60 per cent less, and the fuel delivered under the boiler costs less than $5 a ton. If these facts are borne out in practice, it is clear that there is a large and immediate field for such fuel.

About one-seventh of the total peat lands in the United States are located in Michigan and experiments being conducted at Chelsea, Mich., by G. A. Willmarth, a peat engineer, are scarcely less interesting than those going on at Minneapolis. Mr. Willmarth has turned his attention to the production of coke from peat and has succeeded in making a product of commercial value, which can be used to replace the expensive charcoal made from hardwood, and in making a peat fuel with a heat value claimed to be over 13,000 B.t.u., surpassing bituminous coal and equaling anthracite in heat value.

In this process only a part of the peat is artificially dried and this is turned into coke and ground with the raw peat. This serves to break up the water cells. The mixture is molded into briquets by a special machine and these are air-dried in sheds. The process, briefly, is as follows:

A coking retort is filled with air-dried peat and fire started in the usual way. Then, as raw peat is taken from the bog, it is first run through a disintegrator, a heavy machine that has two rolls, 12 by 22 inches, with tool-steel cutting bars extending from the rolls and running at speeds of 100 and 900 revolutions, respectively. As the peat passes between these rolls it is at once crushed and cut up, together with all foreign substances.

Then it is elevated to a hopper over the "pug mill," which cuts and grinds the peat to a loose granular form. Thence it is sent to a dryer, specially designed for the purpose. It is a drum 3 feet in diameter and 12 feet long, having parallel strips on the inside for lifting the peat as the drum revolves and dropping it upon adjustable slotted disks. Waste heat is drawn from the retort, together with the hot gases from the gas engine and these are forced through the drum by a fan and pass off out the smokestack. The peat, when it reaches an air-dried condition is discharged to the hopper above the retort.

After the retort is filled and the fire started, the gas and tar rapidly pass off to a purifier and scrubber. The scrubber is an upright tank, partly filled with coke, which is sprayed continuously with water. The gases are drawn upward through the coke and the tar is removed by the spray, the gases being forced into a gas holder by a centrifugal pump.

The retort holds 72 cubic feet or 1,440 pounds of air-dried peat, and this will make 8,500 cubic feet of gas, 10½ gallons of tar, and 650 pounds of coke, or 800 pounds of half-coke. The gas is used for power purposes, heating, etc.

The coke, which is then about one-half the weight of the peat used, is elevated to a hopper in which raw peat, which has been disintegrated, is also placed. After being thoroughly mixed and ground in the pug mill, it is sent to the smooth roll grinder, which is a heavy machine having two adjustable steel rollers, 12 by 22 inches, running at different speeds, so that the coke is crushed with the peat.

Here is really the secret of the whole process. When the granules of the coke are crushed with the raw peat, the minute water cells are broken. The plas-

**Weber Crank-Pin Re-Turning Tool**

**No Filing**
**No Offsetting**
**No Jigs**

This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

**SAWYER-WEBER TOOL MFG. CO.**
**353 S. Alameda St. — Los Angeles, Cal.**

**CORD TYPE TIRES**
**Standard Make Inner Tube FREE**
**8000 MILE GUARANTEE**

We are introducing a new reconstructed, reinforced cord type anti-skid tire in one design only. Perfectly moulded with live snappy rubber and all tires are true and uniform (not sewed or seconds). These carry the usual guarantee, and in addition as an appreciation of your first order we will include with every tire one standard tube FREE. Every car owner should send for a trial order. They give by far the most miles per dollar spent and add attraction to every car.

**WRITTEN GUARANTEE IN EVERY TIRE**

tic mass is then pressed into bricks on a special machine and these are conveyed to sheds, where they dry very quickly. Used for heating purposes exactly as coal would be used this fuel is said by persons who have used it to be a superior product. It is easily kindled, burns freely and gives an intense heat. If the drafts are closed it will keep fire for a long time and when the drafts are opened a good fire will be had almost immediately. It is cleaner than coal and more easily managed. There is very little smoke and no soot and it leaves no clinkers, only a soft light ash.

Some fifteen years ago a number of highly ingenious but useless machines were designed and built in this country for the manufacture of peat briquets. The inventors failed, however, to take into consideration the nature of the raw peat and without exception their product was a commercial failure. The public was induced to invest thousands of dollars in these enterprises and undoubtedly this experience has had a great deal to do with the lack of progress here in recent years.

### Taming the River Nile

(*Continued from page 524*)

storage, the Blue Nile to irrigate Soudan, sounds easy enough, but political considerations immediately came into the picture. The government of the Soudan is double-headed. The country is called a condominion because it is part Egyptian, part English. It flies both flags. England had to have a hand in it after the affair which culminated with the loss of Gordon at Khartoum, and she made the country partly English by force of arms. All its officials are English. But the Soudan is not Egypt and Egyptians stood aghast at the proposition to dam the sources of the Egyptian Nile proper. The Blue and White Nile dams were threats to throttle the very life of Egypt before ever it got to Egypt. Moreover, Col. M. R. Kennedy, Chief of Public Works of the Soudan, expressed a belief there was not enough water for all the proposed dams and irrigation, and that the end would be a robbery of Egypt.

Nevertheless, war knows no pity and little equity. England could not wait and passed a bill, gave Soudan the money and the Blue Nile dam was begun to supply water for cotton to be farmed by an English syndicate.

There was a politico-irrigation cyclone immediately. Willcocks and Kennedy made charges, even criminal charges, against MacDonald, saying among other things that he had falsified water records to get the bill through, and the Fellaheen of Egypt, who knew little of politics but much of water and dams and irrigation, stirred up such a row that to settle matters, commissions were appointed to investigate, three of them in succession. The first two were neither listened to nor honored—the first because only bureaucrats were members, the second because the decision was against Egypt. To still the noise, England appointed a third commission.

Egypt and her Fellaheen had protested so loudly against unfair commissions that this commission was to be unprotestable. And Egypt and the Fellaheen had heard both of American irrigation, of American engineers and their startling ingenuity, and Egypt and the Fellaheen believed in the land of the square deal and fair play. So England invited America's leading irrigation expert to form the third member of the Nile Commission, and Mr. H. T. Cory, the "boss of the Colorado River," who made the Imperial Valley the "Egypt of America," became the third member.

The Nile Commission met in Cairo in February of this year and under Judge Booth in a mixed court in Cairo took sworn testimony for four weeks as to the charges against Sir Murdoch MacDonald and finished with going over the project physically as well as by plans and testi-

# Tobacco Teeth
## See the change in ten days

Smokers' teeth discolor more than others, usually. But the stains lie in a film, and removing that film removes them.

There is now a way to combat this film. Millions of people employ it. Leading dentists everywhere advise it. See how teeth whiten when you use it a few days.

### Film ruins teeth

That film on teeth which makes them dingy causes most tooth troubles. It is viscous—you can feel it. It clings to teeth, enters crevices and stays.

The old ways of brushing did not end it, so millions found that well-brushed teeth discolored and decayed.

It is the film-coat that discolors, not the teeth. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.

Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea. Very few people have escaped these troubles caused by film.

### Now we combat it

Now dental science has evolved ways to combat film day by day. Able authorities have amply proved their efficiency.

These methods are combined in a dentifrice called Pepsodent. Millions have adopted it, largely through dental advice. It opens, we believe, a new dental era. And, to let all know it, a 10-Day Tube is being sent to everyone who asks.

### See and feel it act

Pepsodent brings five desired effects. Some are instant, all are quick. A very short test will prove a revelation.

One ingredient is pepsin. Another multiplies the starch digestant in the saliva, to digest starch deposits that cling. It also multiplies the alkalinity of the saliva, to neutralize the acids which cause tooth decay.

Two factors directly attack the film. One of them keeps the teeth so highly polished that film cannot easily adhere. With every application it combats the teeth's great enemies as nothing else has done.

Send the coupon for a 10-Day Tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how teeth whiten as the film-coat disappears. Let this test show you, for your own sake, what clean teeth really mean.

**Pepsodent** PAT. OFF. REG. U. S.

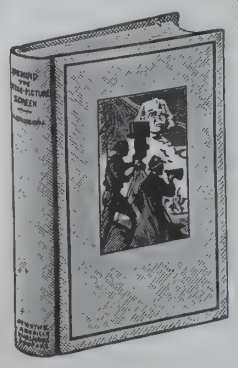
A New Book on a New Subject

**BEHIND THE MOTION-PICTURE SCREEN**

*By* AUSTIN C. LESCARBOURA

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.



Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Size 6¼ x 9½. $3.50; postage—15c in the East, 20c to Chicago, 30c to the coast.

*One of the Most Attractive Books Ever Issued.*

mony. The charges against MacDonald were found to be without basis; it was ascertained there was water enough for all, and, on a strictly engineering basis, the projects were recommended to go forward to completion.

Briefly, these huge engineering works include two dams (now under construction) a storage on the Blue Nile of nine million acre-feet of water, and a canal, to abort the swamp in the Sudd region which now absorbs the greater part of the White Nile flow. The White Nile has its rise in Lakes Albert and Victoria, and if the swamp loss is cut off the storage in these lakes will be vastly increased. But the canal will be 225 miles long and twice the excavation yardage of the Panama Canal. When finished the whole project will conserve eighty per cent of the mean annual flow of the Nile, will cost fifty million Egyptian pounds ($250,000,000), will irrigate 10,000,000 acres (double the present acreage), and put five million acres in cotton. As a measure of comparison let it be said that in the United States we irrigate 32,500,000 acres.

## Keeping Tabs on Bird Peculiarities

(*Continued from page 525*)

only when a bad storm indicates the permanent approach of colder weather. Bird banding work has been under headway for some time in England, Germany and Denmark so that the data from abroad, in many instances, will be available to check the findings ascertained in this country.

By the location of feeding and registering stations along the migratory routes, the government authorities hope to obtain interesting data concerning the speed of migration as well as the affinity of birds for certain nest sites. For many years people interested in bird life have contended that the same birds returned to the same nest each year. If this is true it indicates that a pair of birds will mate for life. Uncle Sam is anxious to ascertain definite facts in this regard. Considerable is known about the habits of the different species of land birds but little is on official record relative to the characteristics of the individual birds of the different families. For example, the class characteristic of the cardinal is to fight and squeal when first captured. However, several cardinals have been snared by representatives of the Biological Survey which displayed neither of these qualities but which were extremely docile and tractable as soon as they were captured.

Some birds acquire full plumage in a single year. Others, like the oriole, take several years to develop their permanent overcoats of feathers. A certain variety of the heron family which breeds commonly in the southern swamps in juvenile plumage is always white, while in adult garb its dress changes to blue. Peculiarly enough, some of the birds of this species at the age of about one year display what is known as calico plumage—a mottled kind of white dress. It is only through a comprehensive and continuous campaign of banding and registering the birds in all sections of the country, such as that to be inaugurated by the Federal Government, that complete and definite data concerning the why, when, where and how of bird doings will be collected and correctly interpreted.

Mr. S. Prentiss Baldwin of Cleveland, Ohio, and Thomasville, Georgia, has conducted some of the most important bird-banding and systematic trapping investigations attempted in the United States. He reports that of over 5,000 or more birds which he has handled during the last five years not more than five have been seriously injured in the traps. His experiences indicate conclusively that the birds are, in no respect, harmed by the trapping and banding and that really the handling helps to tame the birds. The greatest source of damage to the captive birds are cats and that is why it is necessary to surround each trap with a guard fence which will prohibit these felines reaching the cages and worrying the birds.

The bird student who desires to essay bird feeding, banding and registering should first of all carefully scrutinize the game and bird laws of his State and ascertain positively from the local authorities whether the temporary catching of the birds for banding and registering constitutes a technical violation of the State laws. If necessary, it may be advisable for the enthusiast to secure a collector's permit in States where the local legislation is opposed to bird trapping. In the main, the feeding and protection accorded the birds by the people interested in studying their intimate habits and peculiarities completely overbalance any of the very rare injuries which result as a consequence of the fliers being held for short periods in captivity.

## How Meadow Mice Destroy Trees

(*Continued from page 525*)

In the maple collection nearby at least two trees have been destroyed, and four Japanese maples in the Fruticetum have been girdled. In the case of one of the latter many of the lower limbs were covered with snow and these were entirely stripped of their bark. In the hawthorn collection, also, several trees have suffered in this way, but none appear to have been girdled.

Two lindens, one poplar, several wild cherries, and other trees scattered about the grounds have likewise suffered, but not to the same extent as the shrubs.

In the lilac collection recently installed on Pelham Parkway, containing many fine French varieties, between thirty and forty plants have been destroyed. In the weigela group north of the lake near the museum building twelve of the large clusters have been completely girdled; while at the Mosholu Approach and elsewhere, the weigelas have suffered severely.

The Georgia syringa collection is planted in a low spot in the Fruticetum, where there is much grass and the snow lingered long. Here the mice camped among the stems a foot or more above the ground and played havoc with nearly every one of them, eight large clumps being destroyed. The oriental sweet shrub on the bank above seemed to be especially attractive to the mice, eight of these clusters having been destroyed.

A group of deciduous holly was wiped out, shrubs of the pea family, privets, willows—almost anything within reach seemed acceptable to this small, lurking enemy, which is so difficult to combat. Nor was the loss confined to one locality. Reports from other sections indicate that the destruction by meadow mice last winter was much worse than ever before recorded. Toward the end of April I had an opportunity to see some of this destruction in the orchards about Yama Farms in Ulster County, New York. In one orchard visited, containing several hundred apple trees just coming into good bearing, not a single tree was spared. All of them were girdled clean for a space of from one to two feet above the ground.

Bridge grafting is often recommended to save trees not entirely girdled. Strips of fresh tissue are inserted during April, when growth is actively beginning and before the wounds have dried out, and the descent of food to the roots is thus insured. A tree wounded near the base, however, is always liable to attack by fungi, this being a very vulnerable point.

On May 6 I visited the grounds of the International Garden Club in Pelham Bay Park and saw beautiful climbing rose bushes trained against a wall, gnawed clean by mice for a distance of three feet above the ground; and in a group of about thirty Japanese maples, twenty-one were girdled beyond hope of recovery. In a field near by, black locust trees over a foot in diameter were completely girdled although the inner bark of this tree is considered poisonous to horses.

# from GUESSWORK to a SCIENCE

***How the Chart established America's Supremacy in Scientific Automobile Lubrication***

"EVERY great scientific truth," said Agassiz, "goes through three stages. First, people say it conflicts with the Bible. Next, they say it has been discovered before. Lastly, they say they have always believed it."

You may not realize that scientific automobile lubrication has passed through three somewhat similar stages—indifference—passive acceptance—active endorsement.

Fifteen years ago the Vacuum Oil Company organized its study of motor car lubrication. We were the first to take up in a scientific manner the lubricating problems of all makes of motor cars.

As a result of careful analysis and experiment there was formulated the first Chart of Recommendations ever made for automobile engine lubrication. Although there were then only about 125,000 motor cars on the roads, the Vacuum Oil Company foresaw the immense possibilities of the automobile. They felt keenly that more might be properly demanded of an oil than "that it kept the car running all right."

By the fall of 1906, the first Chart was complete. In January, 1907,the Chart was ready—in booklet form—for general distribution.

The Chart in two respects was revolutionary. It specified different grades of oil for different cars. In some cases it specified a different grade of oil for winter use than that recommended for summer.

In its early history the Vacuum Oil Company Chart of Automobile Recommendations did not escape belittlement. But by the sheer soundness of the scientific principles advanced, and by the sheer quality of the grades of Gargoyle Mobiloils provided, the outcome was never uncertain.

## Chart of Recommendations *for* AUTOMOBILES

(Abbreviated Edition)

### How to Read the Chart

THE Correct Grades of Gargoyle Mobiloils for engine lubrication are specified in the Chart below.

A means Gargoyle Mobiloil "A"
B means Gargoyle Mobiloil "B"
E means Gargoyle Mobiloil "E"
Arc means Gargoyle Mobiloil Arctic

These recommendations cover all models of both passenger and commercial vehicles unless otherwise specified.

**The Chart first appeared when touring cars were advertised as "double phaetons"—when the fashionable automobile was characterized by red paint and a great deal of exterior brasswork.**

Today no one longer questions the soundness of the advice given through the Vacuum Oil Company's Chart of Recommendations. This Chart points the way to scientific automobile lubrication the world over. Over a million copies have been distributed in the United States during 1920. Hundreds of thousands of copies are in active use in all parts of the globe.

The Chart, and the several grades of Gargoyle Mobiloils have thus established America's supremacy in the field of scientific automobile lubrication.

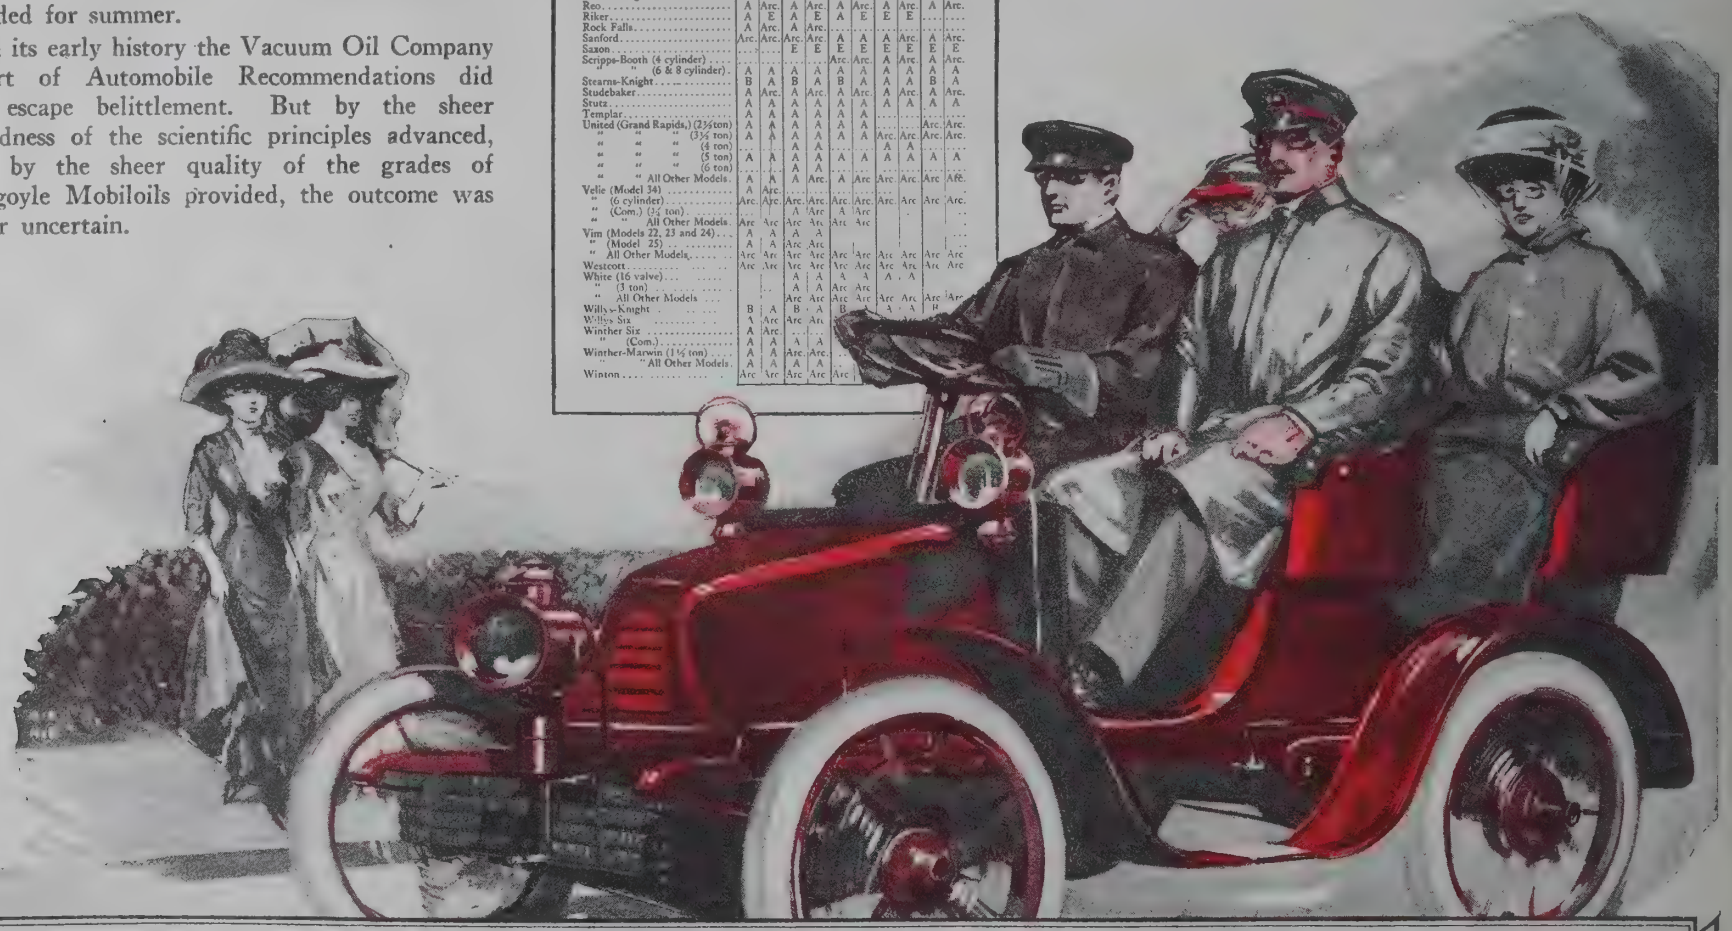
To follow the Chart is to admit that science and experience count in automobile lubrication as well as in other fields of endeavor.

If the partial Chart shown here does not list your car, send for a copy of our book "Correct Automobile Lubrication," which contains the complete Chart. Or consult the complete Chart at your dealer's.

GARGOYLE

# Mobiloils

*A grade for each type of motor*



# VACUUM OIL COMPANY

*Specialists in the manufacture of high-grade lubricants for every class of machinery. Obtainable everywhere in the world.*

# NEW YORK, U.S.A.

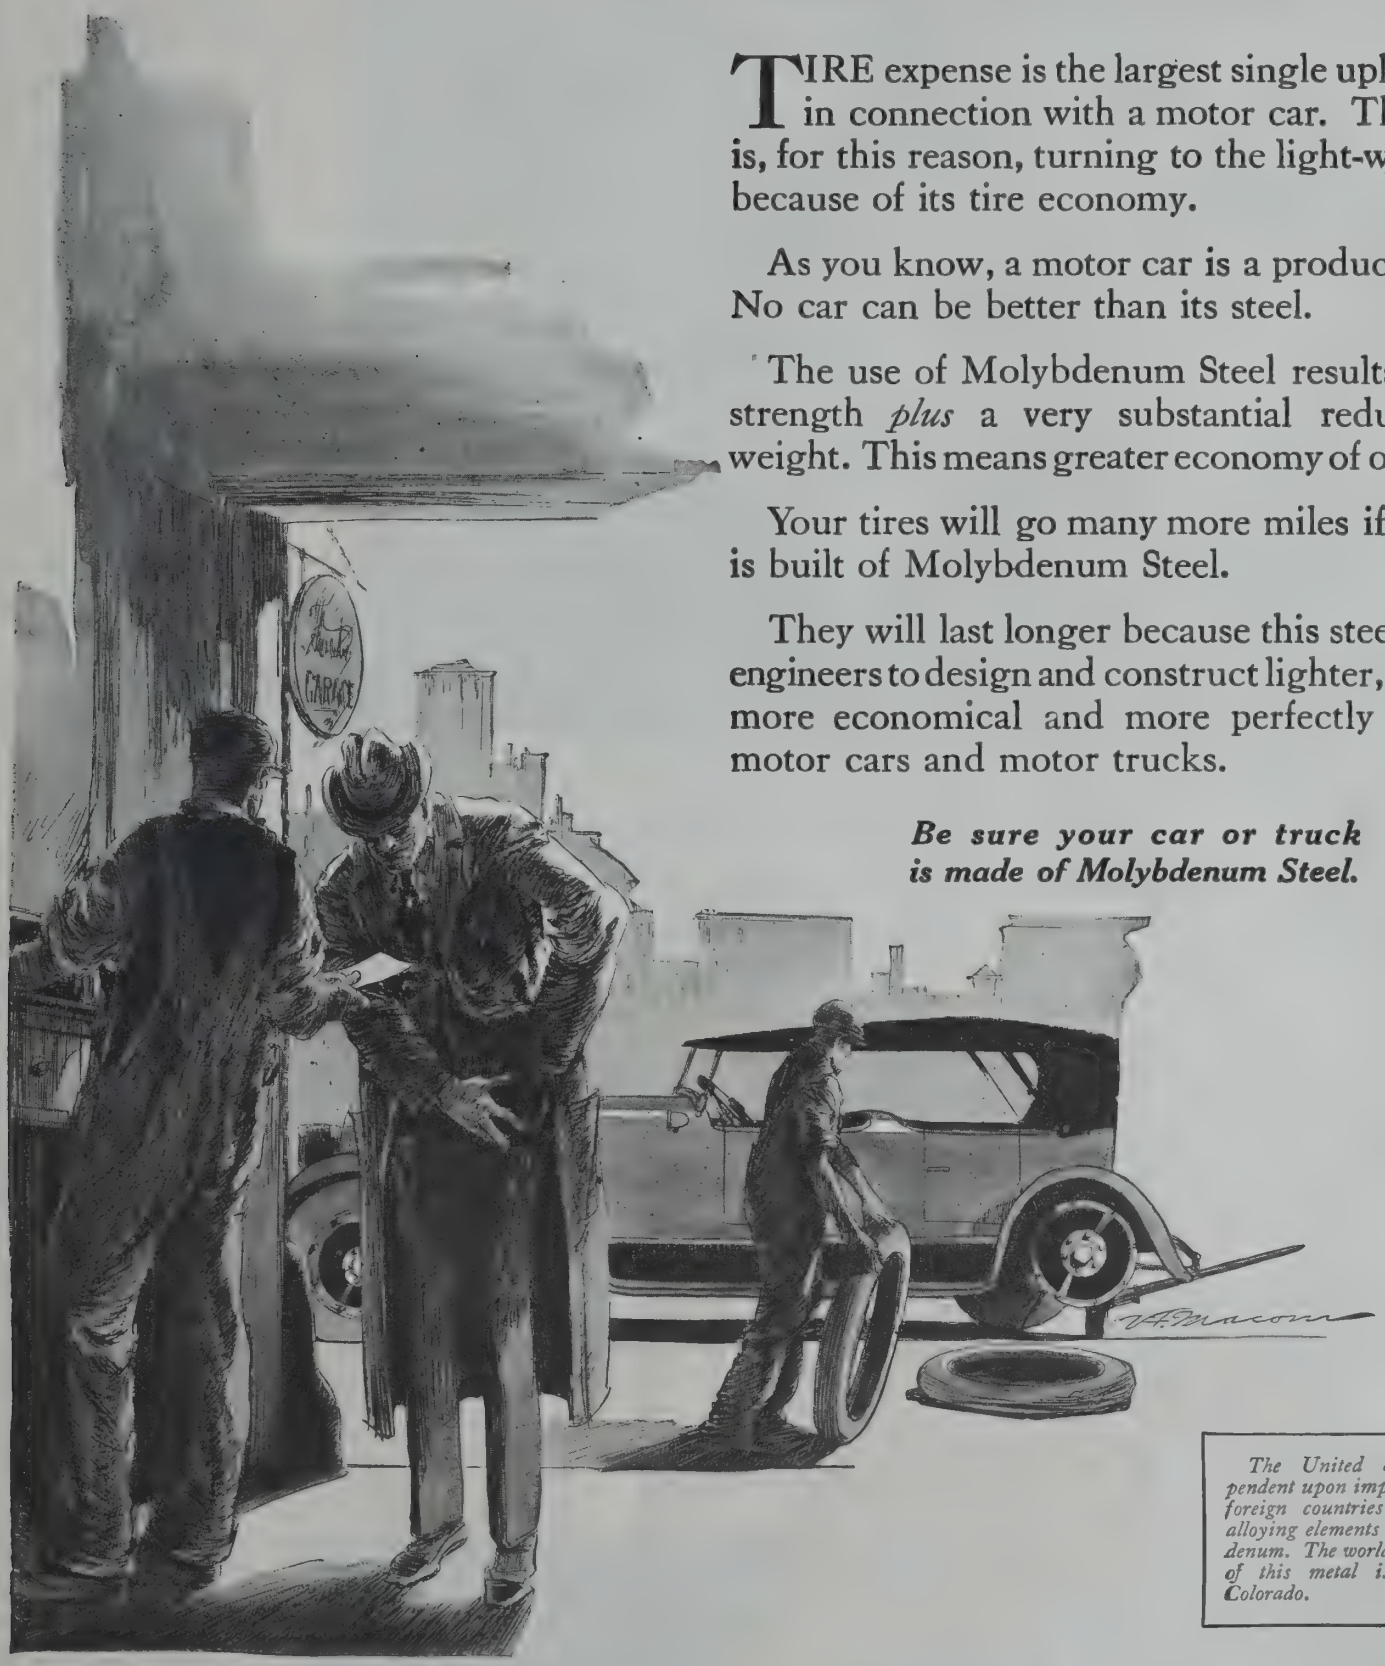
***Domestic Branches:*** New York, Boston, Philadelphia, Pittsburgh, Detroit, Chicago, Minneapolis, Indianapolis, Kansas City, Kan., Des Moines

# Mo-lyb-den-um Steel

## *The American Super-Steel*

*and*

## YOUR TIRE BILLS



TIRE expense is the largest single upkeep item in connection with a motor car. The public is, for this reason, turning to the light-weight car because of its tire economy.

As you know, a motor car is a product of steel. No car can be better than its steel.

The use of Molybdenum Steel results in extra strength *plus* a very substantial reduction in weight. This means greater economy of operation.

Your tires will go many more miles if your car is built of Molybdenum Steel.

They will last longer because this steel permits engineers to design and construct lighter, stronger, more economical and more perfectly balanced motor cars and motor trucks.

***Be sure your car or truck is made of Molybdenum Steel.***

*The United States is dependent upon importations from foreign countries for all steel alloying elements except Molybdenum. The world's chief source of this metal is at Climax, Colorado.*

CLIMAX Mo-lyb-den-um The Commercial Alloy

**Climax Molybdenum Co.** *associated with* **The American Metal Co., Ltd.**

*61 Broadway —— New York*

*Climax Molybdenum Company is the largest producer of Molybdenum in the World.*

# Lighting the Pathway of Human Life

LIFE'S shadows lengthen. Twilight is at hand, and man's senses falter. Nature, calling for help, must be heeded, or happiness is threatened.

Particularly true is this of the sense of sight, most important of all to human comfort. When eyes grow dim, optical science must come to their rescue. Supplementary lenses, expertly ground of glass and skillfully applied, must re-enforce those provided by Nature.

Again, to eyes proven faulty at the morning or midday of life this co-operation of optics is even more vital. Many a defective child has been placed on an equal footing with his school fellows by a right application of glasses, has been given the opportunities and pleasurable sensations which life owes him. Many a workman has been transformed from inefficient to efficient.

While immediate responsibility for this service rests with the eye specialist, he must be given suitable lenses, with which to work, or his skill is helpless. To provide such lenses is one of the endeavors to which our resources have been consecrated since the establishment of our business nearly 70 years ago.

When John J. Bausch opened his little optical shop in 1853, all lenses were imported from Europe. Dissatisfied with the quality Europe was giving him, he made a lens-grinding machine and began to grind his own by hand, crudely but well. So well, in fact, that his product soon attracted the attention of other opticians, who sought him out to demand his surplus for themselves.

And so Mr. Bausch and his colleagues have been making superior lenses ever since, in almost unbelievable quantities, for the exacting optical men, not only of America but of all countries of the civilized world—scientifically developing the various types required for the correction of every kind of eye error. Nor has their service stopped here. They have come to produce, as well, practically every known type of optical appliance or instrument for the conservation and extension of human vision in science, industry and recreation.

**Details of the coalometer, which detects heat losses in the soft-coal pile, and how it is installed to keep tabs on different sections and different depths of a pile**

## Detecting and Preventing Leakage in the Soft-Coal Pile

By R. P. Nichols

A NEW device for indicating the thermal conditions of stored soft coal will be of interest to those who use bituminous fuel in quantity. For it is a fact that coal deteriorates under certain conditions. Quoting from Porter on "Weathering of Coals," 1915:

"Porter and Brunton also found that a coal pile may be covered with snow, yet 3 feet below the surface of the coal the temperature may be quite high."

The new device, known as the coalometer, was designed for either permanent or removable installations, to meet the conditions encountered whenever soft coal is allowed to lie in storage for an appreciable time, awaiting removal. The instrument in its perfected state was developed from a joint invention of Prof. A. W. Browne, Professor of Chemistry at Cornell University, one of America's leading scientists, and the writer.

As is well known, bituminous coal has the property of spontaneously heating, in certain spots, and at varying depths. This heating does not always cause actual combustion, in the sense that the coal burns with the presence of flame, though this condition is also often encountered. There does exist almost universally, however, in stored coal of this character, a slow combustion which is even more destructive than combustion by flame, owing to the fact that it cannot be so readily detected, and thus accomplishes its destructive heating quietly and unnoticed throughout an ever-increasing zone beneath the surface of stored coal. This slower escape of the valuable B.t.u.'s, for which the consumer pays his money, is equivalent to the actual loss of that amount of heating value from fire or other cause.

Could the consumer look beneath the surface of his coal pile and definitely acquaint himself with conditions existing there, he could save himself enormous losses by using that part of his coal supply first which showed a tendency to become even slightly heated.

It is for the purpose of indicating these conditions beneath the surface that the coalometer was designed. It consists of a set of temperature indicators encased in a long pointed steel tube, carrying at varying depths metal bulbs (corresponding to the bulbs of thermometers), and at its upper end a set of dials and pointers, which indicate under all atmospheric conditions the exact temperature of the bulbs which actuate them. These units are forced down into the coal pile to definite depths and at various points, and collectively furnish definite data to the consumer as to the exact temperatures existing beneath the surface. If an accurate record of these instruments be kept, periodically, the slightest rise in temperature is at once detected, and should it become excessive, the consumer at once removes this particular portion of fuel, thus saving the heating value of the coal which had started to dissipate.

Tests have shown that a coalometer installation of one unit each 50 feet in both directions from its neighbor will efficiently indicate conditions of temperature below the surface. Thus the installation of one triple unit will protect approximately 900 tons of coal if the volume is about 50 x 50 x 16 feet.

The accompanying drawing shows a triple unit coalometer for use in coal piles from 15 to 20 feet deep. A galvanized steel tube, having a hardened steel diamond point drill at its lower end, carries three pressure bulbs at depths of 5, 10 and 15 feet, respectively. Tubes from these three bulbs register temperatures in Fahrenheit degrees upon three dials, by means of pointers provided for this purpose. The scale on each dial starts at 32°F., and is colored black. At and above 120 degrees the scale is red, indicating excessive heat at any point in this zone, and warning the coal man to remove this portion of the coal. The depth of the hot spot is determined at a glance, for the dials are plainly marked 5, 10 and 15 feet, respectively. The dial showing the hottest temperature thus indicates the depth at which the heat is generating.

These dials are enclosed in weather-tight metal cases with thick crystal faces, and the set is again enclosed in a galvanized cast iron case. This furnishes ample protection when in us or in storage.

A slidable pipe wrench is provided on each unit, to aid the rapid and easy boring of the tube to the desired depth. A large, plainly-marked lug, 12 inches below the instrument head, determines the exact depth at which the coalometer is to be placed, and thus allows of no guess work on the part of the man who does the installing. The construction throughout is very rugged, and will allow of the rapid removal and stacking of one or more units repeatedly, without fear of damage to the temperature indicators themselves. These indicators are especially constructed to indicate accurate temperatures under the varying conditions encountered throughout the year. They will indicate exact bulb temperatures regardless of the temperature of the head of the instrument and will retain their calibration under conditions of extreme vibration or violent shocks.

## Our Navy and the Japanese Bogy

MORE than once since the armistice, the SCIENTIFIC AMERICAN has drawn public attention to the fact that, although in agreement with our history and traditions we are the protagonists of disarmament, and have proclaimed ourselves to be the champions of right and liberty as against might and enslavement, yet these same United States are today the only country in the world, with the exception of Japan, that is engaged in warship construction. Moreover, our plans for development are upon such a stupendous scale that we have no less than eighteen capital ships under construction, all of which are of far greater fighting power than those of any other nation.

When the great conflagration burst forth in Europe and some of us urged that we should at once strengthen our naval forces, the Secretary of the Navy, it will be remembered, deprecated strongly any such action. Today, the mighty military orgnization which broke the world's peace in 1914 has been disrupted, its arms destroyed, and its fleet sunk at Scapa Flow or distributed among the victors. Nevertheless, a secretary who, when danger confronted the country refused to make preparation, now, when the threat has absolutely vanished, would not only carry on the huge program of armament devised for a sudden war emergency, but he would even add to the battleship program which we now have in hand.

The SCIENTIFIC AMERICAN can never be accused of favoring a weak-kneed naval policy, or one that carries any color of pacifism. For a quarter of a century we have urged that the United States should possess a navy sufficient for her security and commensurate with her dignity; but we possess some sense of proportion, we hope, and the present situation that this country of all free countries should be engaged in huge military constructions at a time when others have abandoned them, seems to be both illogical and inconsistent with our own national principles.

If we wish to possess the biggest navy in the world just for the fun of it, well and good. But if this determination to build the biggest of all navies, which was first announced in an oratorical flight by President Wilson at the time when the growing wave of enthusiasm aroused by the preparedness movement was at its height—if this resolve, we say, is serious, the question arises—having this big fleet, whom do we wish to fight, or who on earth is it that is wishing to fight us? It can scarcely be Great Britain, for, in spite of our announced determination to build a navy bigger than hers, she has not only ceased all battleship construction, but has broken up three or four very powerful battle-cruisers which were under construction. Evidently, she regards the growth of our navy with perfect equanimity and is satisfied that, the Irish question and a certain type of hyphenated Irish-American notwithstanding, America as a whole has no hostile purpose back of her naval expansion.

This brings us to the question of the so-called Japanese threat, that bogy which owed its inception largely to the activities of Captain Boy Ed, the notorious naval attaché, and is now being trotted forth and dangled before the eyes of the citizens of the United States, whenever the Japanese immigration problem flares up a little more than usual in California. Boy Ed, of course, was merely drawing a red herring across the trail which led straight to Wilhelmshafen and the Kiel Canal—the more our Navy Department could be led to contemplate a bogus peril in the Orient, the less thought would it give to the very real peril in the Occident.

We call it the Japanese bogy for the reason that if there is one thing more than any other which the very wise and far-seeing statesmen of Japan regard as altogether out of the question it is that of an attack on the United States. They know full well that, so great is the preponderance of our naval strength that the issue of a naval war would be a wiping out of their fleet as complete as that which befel the German Navy.

## The Tragedy of Our American Forests

CONSPICUOUS among the abundant natural resources of the United States are, or rather were, the vast forests with which our forefathers found the virgin soil of their future country to be covered. There is a universal tendency in human nature when it finds itself surrounded by superabundance to make a lavish and wasteful use of the resources thus presented, and in this the pioneers who went out to possess the country were no exception. They selected for their use that which came most ready to hand, and what they did not use they allowed to run to waste.

It would be unjust to censure our forbears, whether pioneer or lumberman or farmer or miner, for this extravagance. It is doubtful if one per cent of those good people had the faintest conception of the extent to which the growth in population of the United States would reach and how the superfluity of their day might give place to the scarcity of ours—for it is a fact that at the present rate of consumption positive scarcity in certain of our natural resources is within measurable distance.

A recent report of our Forest Service reveals the disconcerting fact that already three-fifths of the original forests of the United States has disappeared. Furthermore, we are cutting our forests at the rate of 26 billion cubic feet of wood per year, and by way of replenishment to make good that loss in reforestation, we are growing less than 25 per cent as much timber as we are using, or, to be exact, we are providing for increase only at the rate of 6 billion cubic feet per year. Any one can see that there can be but one issue to such a policy, namely, the absolute wiping out of our once magnificent forests. Just what effect this will have upon the appearance of the country may be judged from a visit to some of the eastern countries that were once rich with forests but now, because of the total lack of renewal by reforestation, present a series of hills and valleys absolutely barren of timber.

This report of the Forest Service tells us that the depletion of our timber resources has not resulted primarily from the use of our forests but from their devastation. There are vast areas of forest lands that are not producing the timber crops which they could produce and should. Thus, there are 326 million acres of timber lands through which the lumberjack and the sawmill have passed which today are bearing absolutely no saw timber. Some of this big acreage is completely devastated. A part of it is partially restocked with trees which, we are told, are of inferior quality, while there are comparatively limited areas only which are growing new timber at their full capacity.

By way of remedy, the Forest Service makes the following suggestions: First, coöperation with States in fire prevention and forest renewal; second, extension of Federal forest holdings; third, reforestation of denuded Federal land; fourth, a study of the question of forest taxation and insurance; fifth, a survey and classification of forest resources; and, finally, appropriations for forest research.

Many times down through the years the SCIENTIFIC AMERICAN has urged upon the country the need for taking hold of this problem in an enlightened and patriotic manner. The time for action is already very late; but if we apply ourselves to the task with intelligence, energy and liberality, there is yet time to save these forests and build them up to some of their original splendor.

## The Scientific Voter

THE first Tuesday after the first Monday in November has passed into history with the usual after-symptoms on the part of the Great American Press, varying according to political complexion. The organs that had supported the winners have pointed with customary assuredness to the vindication of their party's high moral purposes; while those whose wishes were not synchronous with the desires of the majority have as usual fallen back upon the future to reveal that they were really right all the time and that the voters will be sick of their bargain before they are through with it. There has been the usual solemn poppycock about the voters having been misled by minor bones of contention so that their verdict is not to be construed as a judgment upon what the particular scribe of the moment considers to have been the major issue; and we recall no campaign in many years in which the losers were quite so well resigned to turning over the ship of state to the winners and letting them try their luck at steering it for a while.

But all this is wholly normal. There is, however, one feature of the 1920 elections which, while in full accord with the trend of the past forty years, has this year attained a development altogether extraordinary.

Of course the whole tendency of the present-day electorate is away from the rigid party demarcation which was once so universal that the mere suspicion of not having swallowed the ticket whole was enough to make a man an outcast in the social as well as in the political community. But the persistence with which the old tradition hangs on is at times discouraging. The splitting of a ticket is not necessarily an indication of sagacious choice, to be sure; but it is at least an admission that the voter is willing to attempt such discrimination. Hence by the amount of ticket splitting indulged in rather than by our own personal impressions of its success in seating good men and rejecting bad ones must we judge the extent to which the American voter is willing to attempt the exercise of judgment in marking his ballot.

We need go no further than New York State to realize that on this ground 1920 marks an epoch. It is true that in certain previous campaigns the State officials elected have been divided between the two parties; but this has happened only in years where the vote was so close that the shift of a few thousand votes would cause the candidate for, say, State Engineer and Surveyor against whom there was local feeling in some parts of the State, to run far enough behind his successful ticket to lose out himself. It is likewise true that for several years the New York voter has been confronted with a ballot which deprives him of the opportunity of voting a straight ticket with a single X, and forces him to mark individually each candidate for whom he would vote, regardless of whether these are or are not all of one party. But this merely meets the physical problem of marking the ballot, and touches not at all the mental one of deciding how to mark it; it is still far easier to make up one's mind to vote for all the Republican or all the Democratic candidates than to form and carry into the booth and put into execution a decision to mark certain names to which the star is attached and others that follow the sign of the rooster.

The bald fact on which we comment is this: Mr. Harding carried New York State by more than a million votes; Judge Miller, running for Governor on the same ticket, registered a plurality of a mere 70,000. In round numbers, the present Governor "Al" Smith ran a million votes ahead of his ticket. That this is a great tribute to Mr. Smith's personal hold on the voters is evident; but this is not the aspect that we would emphasize. If anybody had predicted, on election morning, that anywhere in the United States any candidate could by any possibility run a million votes ahead of his ticket, such prophet would have been laughed to scorn. The thing had never been done and never would. Yet it was done; in this one State alone, at least half a million voters attempted, regardless of party affiliations, to discriminate between the candidate they wanted and the one they didn't want. We submit that this is a most encouraging sign pointing toward a future when it shall be less than ever possible to fool any great number of the people for any considerable proportion of the time.

## Electricity

**Telephoning Over High Tension Lines.**—An Eastern gas and electric company has been obtaining excellent and quite practical results with directed radio or wired wireless over its 11,000-volt lines between Ocean City and Atlantic City, N. J., a distance of twelve miles. The terminal apparatus may be connected with any part of the electric system—the 110-volt lamp or 2,300-volt buses.

**Dust and Lighting Fixtures.** — When figuring on the installation of new lighting equipment it must be remembered that when the lamps become old and more or less dirty between cleaning periods the emitted light falls off about 25 per cent, according to *Electrical World*. Consequently for a desired foot-candle illumination the rating of the lamps must be about 33 per cent higher than that found necessary from calculations based on the efficiency of new clean lamps.

**Again—Electrolysis.**—During the past four months the Bureau of Standards reports that it has carried out in coöperation with the American Committee on Electrolysis, which represents the national utility associations, a number of somewhat extended investigations in the field of electrolysis mitigation in several Middle Western cities. This work has been confined largely and almost exclusively to the effect of pipe drainage on underground systems, especial attention being given to the possibility of joint electrolysis on high-resistance joints and interchange of current between drained systems. Some attention has also been given to the three-wire systems of power distribution and also to automatic substation installations as a means of electrolysis mitigation.

**Bowl Enameled Lamps.**—Rising standards of lighting intensities for increasing production in industries demand the use of larger lamps. As the size of lamps is increased there is greater brilliancy of light source and additional precaution must be taken to ensure diffusion and to avoid glare. The bowl enameled lamp has been developed for this purpose. It has a considerably lower brightness than other forms of diffusing bulb lamps and therefore gives better diffusion and can be viewed with a greater degree of comfort. When used with a reflector the enameling acts as a small semi-indirect bowl placed immediately below the filament and softens all shadows. Bowl enameling is a translucent coating of smooth white material sprayed on the bulb. It will not chip, crack or discolor and is not subject to depreciation when exposed to acid fumes, according to the manufacturers.

**Something New in Selling Lamps.**—We are indebted to *Electrical World* for these few words regarding a highly ingenious device for displaying lamps. A St. Louis company has built a wheel 20 inches in diameter on the periphery of which are mounted twenty porcelain receptacles. One side of each receptacle is wired to a common point inside the hub and the other side is connected to a segment of a device similar to a commutator. Energy is supplied to the wheel by means of brushes, and the brush on the commutator is wide enough to light two lamps at one time. The wiring and electrical connections are concealed in the wheel, and its support is mounted on the wall at a point convenient to the lamp counter. The lamps placed in the receptacles range in size from 10 watts to 100 watts of the types most frequently sold. Any desired lamp or two adjacent lamps can be lighted at will. With these arrangements the comparative size, style, and brilliancy of lamps can easily be shown to a customer and the order filled directly from stock.

**Good Work, Italy!**—Since the signing of the armistice Italy has resumed her industrial life with considerable rapidity. She has not been free from the uncertainties of radical political action, but there is every evidence that these are on the decline; Italy is at work as completely as any nation in Europe and more so than most of them. Her wealth in hydroelectric possibilities is being developed at a rapid rate. Energy for industrial purposes, while absorbed as quickly as it is produced, is extremely cheap, and in a few years it will be abundant and the whole country interlaced with transmission lines. The various companies engaged in this work are well financed and are working harmoniously in both plant and line extensions, continues *Electrical Review*. The men engaged in this business are young, energetic and capable business men, highly representative of the new spirit that has possessed the industrial life of the country. The electrification of the Italian railways now proceeding involves 4,000 miles of additional trackage. The cost of the energy is not so great a problem as the cost to the government of converting the necessary equipment, but the mileage already converted is considerable and the equipment is of a very high order.

## Science

**A New Science Center in Washington.**—Some time ago the Carnegie Corporation of New York provided funds for erecting in Washington a building to serve as a home for the National Academy of Sciences and the National Research Council. Subsequently a number of individual patrons of science contributed a fund of $200,000 for the purchase of a site, which has now been secured. It comprises the entire block bounded by B and C Streets and Twenty-first and Twenty-second Streets, Northwest, facing the new Lincoln Memorial in Potomac Park.

**Agriculture Over Frozen Soil.**—One of the peculiar features of agriculture in Alaska has recently been described by the Department of Agriculture. In the Tanana Valley, the chief farming district of the territory, the average annual rainfall is only about 12 inches, which would ordinarily make dry-farming methods appropriate, but the first few crops raised after a tract has been cleared in this region get plenty of moisture from the melting of subterranean ice. In the course of a few years, however, the ice recedes to a depth of 6 or 7 or more feet, and no longer supplies moisture to the crops. It is then necessary to use machinery which will not only pack the soil a few inches below the surface and thus hinder evaporation, but also maintain a surface mulch of loose soil, which further checks evaporation.

**Chemistry in the Newspapers.**—The news service maintained by the American Chemical Society reports that a very gratifying amount of attention was given by the daily newspapers to the recent 60th meeting of the society, in Chicago. Although the meeting occurred in the midst of a political campaign, the Chicago papers devoted about 10 columns to it, and extensive despatches sent out by the press associations were widely and prominently printed. The technical director of the A.C.S. News Service says: "The subjects which seem the most popular to date, as far as lay journalism is concerned, are flavoring extracts without alcohol, the resolution urging Congress to pass dye legislation, hydrolyzed sawdust as cattle food, all news relating to fuel and news print paper, and the announcement that America now makes 800 rare chemicals, this last being featured on the front page of the New York *Times*."

**Exploring the Upper Air in the West Indies.**—During the past hurricane season in the West Indies the U. S. Weather Bureau has carried out a program of upper-air observations in order to determine what relation, if any, exists between the "winds aloft" (as winds in the upper air are now called by the Bureau) and the movements of hurricanes. Pilot-balloon observations have been made twice a day at stations maintained by the Bureau at Key West and at San Juan, Porto Rico, and at stations maintained by the Navy at Colon and Santo Domingo; while the data obtained at the Weather Bureau and Army aerological stations in Texas are expected to help in the investigation of this subject. While the chief purpose of the undertaking was to aid in the important work of forecasting West Indian hurricanes, the discussion of the observations will probably furnish much-desired information concerning the normal circulation of the atmosphere in the West Indian region.

**Dr. Albert Einstein** has not, according to *Science*, abandoned his chair at the University of Berlin, but he has accepted an appointment at the University of Leiden and will divide his time between the two institutions. Much interest has recently been aroused by the announcement of the German physicists, L. Grebe and A. Bachem, that they have found the shift of the lines in the solar spectrum which was the third test of the Einstein theory, the others being the motion of the perihelion of the orbit of Mercury and the apparent displacement of stars due to the gravitational field of the sun, as best observed at solar eclipses. The predicted shift is toward the red and is in the spectrum of the sun's edge or limb. By making a careful microphotometric study of three spectograms of solar absorption lines the source of which is now ascribed to nitrogen, Grebe and Bachem were able to select nine lines in the ultra-violet that are free from the contaminating influence of superposed lines of metallic origin. Expressed in terms of the equivalent Doppler effect, the final result was a displacement of 0.56 kilometers per second, which agrees very closely with that predicted by Einstein (0.6 kilometers per second). The displacements of the different lines varied a good deal, but all were shifted toward the red. It is claimed that the discordant and non-confirmatory results previously published by several investigators were due to the inclusion of lines the positions of which were seriously influenced by the superposition of adjacent metallic lines.

## Aeronautics

**Aerial Regulations in France.**—At last the French authorities have drawn up a series of regulations covering the inspection of aircraft, the issue of pilots' certificates and the control of aerial traffic in France, and they are to be embodied in a decree to be published shortly. *Flight* reminds us that they are almost identical with the British regulations, in accordance with the International Convention.

**Our "R-38".**—The work on our Naval dirigible "R-38," being built at Bedford, England, is nearing completion. It is not expected that the voyage to the United States will be made before May, 1921. At that time the hangar at Lakehurst, N. J., will be ready to receive the giant dirigible. With the completion of the huge Lakehurst hangar, the United States will be in a position to construct airships similar to the "R-38."

**An Airplane That Carries Its Own Shed** has recently appeared in the form of the new Sablatnig parasol limousine monoplane, of European conception. This machine is provided with a folding tent which weighs about 75 pounds out of a total 2,200 pounds of useful load. When the planes are folded along the body, the tent covering rests on the leading edges and the propeller tip, thus protecting the airplane against the elements.

**Flying Without the Stick Control.**—By way of demonstrating the possibility of flying an airplane simply by controlling the engine and using the rudder, a French pilot recently made a flight on an 80-horse-power Morane-Saulnier monoplane with the "joy stick" tied up and sealed so that it was impossible to use it. In the presence of officials of the Aero Club of France the machine rose from the ground, circled several times around the Villacoublay airdrome and then made a perfect landing.

**New Italian Dirigible.**—Some weeks ago the new Italian dirigible "Roma" made a trial trip over Rome, proving her airworthiness, so to speak. The airship is of the semi-rigid type, with a capacity of 34,000 cubic meters. It has three pairs of 400-horse-power motors and can travel at from 68 to 74 miles an hour, but one pair of engines will keep up a speed of 56 miles per hour. This, by the way, is exceptional speed for a dirigible. There are rumors to the effect that the United States may purchase the "Roma" and bring it to this side under her own power. Originally, the "Roma" was intended for South America.

**Wholesale Destruction.**—In a recent issue of *Berliner Zeitung am Mittag* there appeared the following advertisement, which speaks for itself: "Destroyed airplane, seaplane and airship engines of different makes for sale in quantities of 1,000 to 20,000. The engines have been rendered useless and must be destroyed further by rendering the crankshafts, crankcases, cylinders, pistons, connecting rods and bearings, push rods, valve gears and carburetors useless, according to and satisfying the instructions of the Inter-Allied Aeronautical Commission of Control. All offers must be handed in before September 1, 1920. Description of how the destroying is to be carried out can be had from the ———" and the name and address follows.

**Germany's Transatlantic Air Station.**—From our British contemporary *Flight* we learn that the German airships which are to carry on the proposed transatlantic service, are to be accommodated in the Isle of Norderney off the coast of Prussia. One of the chief reasons for selecting Norderney is that it is convenient of access to the huge international airdrome projected for Bremen, the distance of 80 miles bringing it well within one hour's time of that air port by airplane service. Five hundred workmen are to be employed for a period of six months in preparing the Bremen airdrome, and the German government has already signified its desire to coöperate by offering a certain proportion of the official out-of-work funds toward wages with a view to securing useful work for the unemployed.

**German Air Mails.**—A regular air mail service was initiated between Berlin and Breslau during the Breslau Autumn Fair week, the distance between the two cities being covered in 2½ hours. The fair closed on September 11th, but the service is likely to be maintained with a view to linking up with the projected Paris-Strassburg-Prague and Warsaw air line. Another interesting development is contemplated in connection with the Berlin-Königsberg air service, continues *Aerial Age Weekly*, which is intended to extend to Reval and Helsingfors—possibly with an eye to Petrograd in the near future. The German postal authorities are also in communication with the Swiss government with a view to the early establishment of a daily air mail between Frankfort-on-the-Main and Basle. Air mails have been running daily between Berlin, Bremen and Wangeroog, and no accident has occurred.

# Making the Barge Canal Pay

## What Is Needed to Give New York's Waterway the Standing It Should Have

By Frank M. Williams, State Engineer and Surveyor of New York

FROM the Great Lakes there are two barge canal routes to the Atlantic Ocean; one by way of the Welland Canal, across Lake Ontario to Oswego; up the canalized Oswego River and by way of Oneida Lake and the Mohawk River to the Hudson at Troy, thence on tide water to New York; the other route is more direct and also less hazardous. It follows the Niagara River from Buffalo to Tonawanda and thence direct across the State of New York to Troy. This route is practically the same as the Erie Canal, the opening of which was celebrated less than one hundred years ago.

The Barge Canal, which is the name given all the channels in New York's new canal system, has been constructed to a depth of 12 feet and the Superintendent of Public Works is required to maintain it to that depth. To do this requires constant attention and much dredging: nevertheless the channel has been maintained at the dimensions required and there is no reason to believe that this cannot always be done without interfering with navigation or hindering the barge fleets. The locks of the Barge Canal, of which there are 35 on the direct route between Lake Erie and New York, give the controlling dimensions for the boats, because barges constructed within the limits of the lock chambers can pass through any other portion of the waterway. These structures are uniform; their usable length is 300 feet and their width 44½ feet. This does not mean that it would be practicable to operate boats 44½ feet wide on the canal for there are other controlling factors. The width in the artificial sections of the channel is 75 feet on the bottom, hence in order for two loaded barges to meet and pass at speed, their width should be something less than one-half of 75 feet, or else passing basins must be provided which would, of course, be the source of considerable delay. Other controlling features are economical considerations. It has been found that there should be a certain ratio maintained between the width of the vessel and the waterway and that this should not be materially exceeded if resistance to the movement of the vessel is to be reduced to a minimum. This ratio varies but may be taken on the average as 1 to 6. With a waterway 130 feet wide, which is the surface width of the artificial sections of the canal, a vessel should be approximately 20 to 22 feet wide. As the new locks are 44½ feet wide it can be seen that two boats of 21 feet beam can be placed side by side in the chamber. The practical length of a boat of that width is 150 feet. Therefore, four barges each 150 by 21 feet can enter and pass through the locks at one lockage.

Practical and economical factors show that barges, on a long, limited depth channel, should not be loaded to more than four-fifths of the full depth of water. This is primarily due to the requirement for a water cushion under the keel so that space will be provided which will allow the operators to maintain a proper speed with a minimum of power. For special purposes larger boats may be used and it is quite possible that as greater experience is had a larger type of carrier may be developed. One of our large shipbuilding corporations has under construction self-propelled barges designed to carry 2,000 tons of freight and it is planned to operate these as single units. Plans have also been prepared for vessels claimed to be designed for lake as well as canal purposes and one of the designers contemplates the construction of carriers 250 feet long and 36 feet wide to move in fleets of four, one being a power barge with 1,000 horse-power. Each of these barges is designed to hold 1,650 tons which would give a total fleet capacity of approximately 6,000 tons. Such a fleet would require four lockages, but it would have the advantage of being able to move safely on the Great Lakes. However, New York's waterway was designed and built as a barge canal and was not originally intended for other purposes. Many believe that the future of the waterway lies primarily in carrying out its original purpose, although they would encourage those who are attempting to construct carriers that can withstand the storms of the Great Lakes and also move through the Barge Canal. Basically, however, the proposition before the designers is one for constructing efficient canal carriers and not adapting canal boats to lake use. Authorities, in making this assertion, have principally in mind cheapness of construction, ease of movement, adaptability to freight, etc. On these grounds they advise that, for all general canal purposes barges 150 feet by 21 feet and having a loaded draft of not more than 10 feet, be constructed. These boats if moved in units of four, one being self-propelled, will move as much freight as three freight trains, consisting of 50 freight cars each and will operate at a rate of approximately 100 miles a day whereas, under normal conditions, freight trains moving low grade commodities average but 25 miles a day.

The United States Government is operating 73 barges and 21 cargo steamers on the Barge Canal. The Inland Marine Corporation has 50 barges and 10 steamers, the

*Left:* Ancient tank, believed to have been built by Pontius Pilate, now recemented and used by the British. Of the two covered pipe lines paralleling the road, one collects water from the spring-houses and the other conveys it to Jerusalem. *Right:* Egyptian labor corps working on the construction of water reservoirs

**Examples of what British administration is doing for the water supply of Jerusalem**

## Jerusalem's New Water Works

**By H. J. Shepstone**

NOT the least of the many blessings which the British have conferred upon Palestine as a result of their occupation of the country is the giving to Jerusalem of an ample water supply. Before their coming the Holy City was virtually dependent upon the rainfall for its water, collected and stored in cisterns. Many of these latter were situated under the houses or at the back of the premises, and generally hidden from view. Water gathered during the rains on the flat roofs was conducted to them by pipes, and there stored until wanted. Many of these cisterns were found to be in a sad state of repair, and, what was worse, were the breeding places of many germ-carrying insects. The military authorities had them all cleaned out and repaired. Some of them had not been cleaned for a hundred years and more.

But these rainwater cisterns were not sufficient to supply the city's needs. Ever since she has been under Turkish rule Jerusalem has suffered from the lack of a good water supply. Except for one small spring, the Virgin's Fount, so named because it is believed the Mother of Christ drew water from it, Jerusalem cannot boast of a single fountain. It is situated outside the city in the Kedron Valley. True, a year or two before the war the Turks built a four-inch pipe from the old Pools of Solomon, to the south of Bethlehem, to the Temple area, but the supply was limited and for the most part reserved for the mosque. Even in Solomon's days the want of water was felt, and he obtained his supplies from three reservoirs built in a valley just below Bethlehem. From these water was brought to the city by an aqueduct.

Over and over again engineers and others offered to repair these reservoirs and build a modern aqueduct, but the Turks always turned the proposition down, or put obstacles in the way, with the result that Jerusalem had to depend upon the scanty rainfall for its water.

It was early in February, less than three months after the capture of Jerusalem, that the British began to grapple with this serious question. They went first to the Virgin's Fount and made an exhaustive study of this historic and interesting spring. As a result, they discovered that it was not an ordinary intermittent spring, but rather a fountain of the character of a geyser, for the flow occurs three to eight times a day, the output varying from 2,000 to 11,000 gallons each time. It was from this very spring that Hezekiah, over 2,600 years ago, conveyed water by means of a tunnel to the Pool of Siloam. Pipes were laid from the spring and water was pumped up to tanks in the Valley of Jehoshaphat, near the northeastern corner of the city wall.

Although this greatly improved matters, the supply was still found to be insufficient to meet the ever growing demands of the city. An examination was now made of the Pools of Solomon to the south of Bethlehem. In the end, however, it was decided to repair and use the old reservoir, now known as Birkett Arroub, lying a few miles to the south of Solomon Pools. It was built by Pontius Pilate and it was from here that he brought water to the city in the days of Christ.

Pilate's old reservoir was repaired and enlarged, its capacity today being 5,000,000 gallons. Galleries were built in various directions to tap the numerous surrounding springs, including those of Ain ed Dirweh, in which, it is said, Philip baptized the eunuch. A powerful pumping plant was installed by which the water is pumped up to large reservoirs built on higher ground on the Hebron road, the water flowing from here by its own gravity in a one-foot iron pipe to twin pools on the hill west of the city, from whence it is conducted to various stand-pipes in and around Jerusalem.

Pilate's aqueduct, ruins of which dot the landscape today, stretched for a distance of forty miles, though as the crow flies the Holy City lies but thirteen miles away. The British pipe line, however, is but fifteen miles in total length. As a result of this enterprise the death rate in the city has dropped by one-half.

## Light Burning in California Forests

**By Charles P. Fryer**

STANDING redwood trees are almost immune from forest fires and this fact necessitates a distinction between the redwood and pine forests in California in any consideration of light burning, a test of which is advocated by the California Forest Protective Association and other private associations and lumbermen for the sake of clearing the forest floor of debris and thus preventing big destructive fires.

In the redwood forests slashings and underbrush occasionally cause fires hot enough to burn to the tops of redwood trees, destroying their branches and foliage but in nearly every case they put out new foliage the next season. This immunity of redwoods to fire is due partly to the climate of the redwood region and partly to the absence of resin in the wood and its thick non-combustible bark.

The primary pine region extends from the Oregon line south through the Sierra Nevada Mountains following closely the line of winter snows and being 2,000 to 3,000 feet above sea level. The timber is in open, park-like stands and in early days the forest floor was kept clear from brush and litter by the light burning practised by the Indians and the occasional fires caused by lightning. The trees passed through several centuries of these fires to make splendid timber.

In these days of close fire prevention and control a rank growth of underbrush has sprung up in California pine forests and there is much debris in places. This causes hot fires which are hard to control and often burn mature trees.

Fire tends to prevent fire as is shown by the small timber losses of 1912 and subsequent years, following 1910, in which year forest fires were the most disastrous known for years in California. Since 1915 the loss each year has been greater than the season before, increasing from less than 2 per cent of the 1910 loss in 1915 to over 60 per cent in 1919, thus showing that the underbrush is accumulating.

**New construction by means of which Jerusalem is freed from dependence upon casual sources for her water**

# One Hundred Years of Gas Lighting

## An Account of the Early Days of This Art, Which First Stood on Solid Ground in 1820

By William Ressman Andrews

THE centenary of illumination by gas practically falls in this year. Eighteen hundred and twenty was the dividing line between the experimental stage of gas lighting and the period of its demonstrated practicability. The history of its expansion is similar to other discoveries in physical science which have developed factors now recognized as fundamental in the advancement of modern civilization.

As in the case of steam and electricity, its practical application to everyday use came long after the researches of the original investigators. Although this general recognition was somewhat tardy at first the progress made in gas lighting was rapid from the time, in 1820, that its merits became thoroughly established. Street illumination by gas was introduced in Paris by Frederick Winsor in that year and thenceforth was extended generally throughout Europe. He organized, some time before, the first gas company in London and was known from the successful culmination of his Paris venture as the "father of modern gas lighting."

In America, too, the feeling, that gas—introduced in Philadelphia and in Baltimore in a tentative way and with some misgivings at an earlier date—had proved to be a practical means of lighting, began to take strong hold on the public mind in 1820. An important improvement which increased the popularity of the new illuminant was made in this year. This was the invention by J. B. Neilson of the Glasgow Gas Works in Scotland, of the "fishtail" burner, or union jet, which gave greater luminosity to the flame. Furthermore it was largely this year which saw the fruitful efforts of scientific men who, having realized the boon of gas lighting, had set forth its advantages in their writings.

Chief among them was Fredrich C. Accum, a Westphalian chemist, living in London, who had published a short time before a "Practical Treatise on Gas Light." This epoch-making work on the subject was immediately translated into French, German, and Italian. The municipal authorities of the continent were at once impressed with the fact that they now had the means at hand to lessen considerably the dangers which from time immemorial had lurked in their streets and alleys after nightfall.

A high degree of pioneer activity characterized the experimental and promotion period. Passing over the earliest events connected with the subject—such as the fitful industry of an ecclesiastical dilettante in England who amused himself by filling bladders with the fumes of coal distilled on the hearth of the rectory kitchen—it was reserved for the experiments of a Scotchman, William Murdock, to point the way to the possibilities of a new illuminating agency. He was the first to show that gas could be made on a large scale for lighting purposes. The experiments were conducted near the close of the eighteenth century at Redruth, Cornwall, where his house was lighted at first by a flame emitted from the crudest form of jet—or rather the absence of a jet. The gas was consumed as it flowed from the open end of an iron pipe. The gas consumption was of course out of all proportion to the volume of light obtained. But he checked the waste by welding the orifice and then boring three small holes in a way to produce three divergent flames. There was now less gas consumed, but the light was poorer. In the next step Murdock flattened the end some little distance down the pipe and bored a number of holes close together along the top. This arrangement produced a series of flame spurts which greatly increased the illuminating power of the burner, called, on account of its shape, the "cockspur."

Shortly afterward the scene of his experiments was transferred to England. The engine factory of Boulton, Watt and Company, at Soho, near Birmingham, was lighted with gas by the Scotch inventor. Its successful application here revealed the fact that the ubiquitous candle and its pushing rival, the whale oil lamp, would be obliged in time to give way before the acknowledged superiority of the new illuminant.

The stage of development which followed was marked by the introduction of a saw-cut across the top of the welded end of the pipe to take the place of the row of small holes. As a result the gas burned in a sheet of flame resembling a bat's wing, and this form of burner was on this account known by that name.

Murdock's later experiments included the adaptation of the principle of the Argand burner, which had a ring of holes at the top of a hollow cylinder through which the air circulated. The draught passing through the center of the cylinder was necessary to insure proper combustion; also the flame, to be of any service, had to burn without flickering, and these requirements were obtained by the use of a chimney.

At first iron tips were employed in the flat flame and the Argand types, but they were soon discarded for tips composed of steatite and similar substances. This improvement came about when it became known that the light intensity depended upon the degree of heat in the flame. Hence the use of non-conducting material for gas tips to keep as much of the heat as possible in the flame itself.

The improvement made by Neilson over these jet forms was based on a simple process. He discovered that the light burned much brighter when two streams of flame were made to strike each other squarely. The impact spread the blaze out into a flat flame. The burner in a short time was universally adopted. The use of clay retorts and the introduction of sulfate of iron as a purifier are other contributions made to the progress of gas lighting by this Scotch mechanical genius.

In another method of purifying gas lime purifiers were employed, the invention of Samuel Clegg, who contributed to an elaborated treatise on gas making brought out by his son in 1850, a volume which proved to be of great value in spreading information as to the advantages of gas lighting. The elder Clegg was also the inventor of a water meter for measuring gas. His device has proved to be the basis of the improvements since made in gas measuring methods.

The year of Neilson's discoveries which evolved the union jet saw the introduction of gas in Boston, and in 1823 there were twenty-three cities in Europe using gas. Berlin, the city from which so much "natural gas" about world dominion was to escape later on from royal lips, began to illuminate its streets and houses in 1826. Dresden followed in 1827 and by 1850 gas had been introduced into twenty-six German cities.

The use of gas in Baltimore dates from 1816; New York, 1823; Brooklyn, 1825; Boston, 1828; New Orleans, 1833; and Cincinnati, 1840.

The New York date is associated with the name of a family long prominent in the business and social life of the city. In that year Samuel Leggett organized the New York Gas Company. It was incorporated at $100,000 and obtained a 30-year franchise to lay pipes south of Grand Street. In September they were laid in the principal thoroughfares and were very different in appearance from the huge metal mains we are accustomed to see nowadays. Wooden logs, laboriously pierced by the primitive tools of the period, and tapering at the ends, served to convey the gas to the point of use. Leggett's house, at 7 Cherry Street, was, according to tradition, New York's first dwelling to be lighted by gas. In 1825 Broadway from the Battery to Canal Street was added to the gas illuminated area.

At that early day in the history of the industry in America, coal was not used for the distillation of gas, except in the anthracite regions. Coal was being shipped from Newcastle and Liverpool and the expense of such importations put coal far beyond the reach of the gas manufacturers who might have been considering its use outside the anthracite sections. Leggett's company distilled its gas from resin, which in his time was cheaply transported by water from the South. The gas fixtures and burners were not made in this country at that period but were brought over from England.

A great advance in gas lighting was brought about by the introduction of the atmospheric burner in 1855, the invention of R. W. von Bunsen. It marked an important stage in the history of gas because it made possible the use of coal gas for heating and cooking purposes.

But a more important invention came from the hands of a man who had been a student under Bunsen—Karl Auer Welsbach, whose burner, known the world over by his name, has achieved a striking and impressive distinction. According to Prof. H. Bunte, in a paper read before an International Gas Congress in Paris, a short time after the Welsbach burner had been introduced in 1886:

"The Welsbach lamp is now the recognized form for both private and public use; the older types are continually losing ground. It has effected a complete revolution, not merely in regard to the illuminating effect and the economy of gas lighting, but even the fundamental factors by which gas is valued and the properties and the manufacture of gas have been entirely altered."

The inverted incandescents, a development of the Welsbach principle, first made their appearance in 1900, and proved to be more satisfactory than the upright lamps. Another strong point in the appeal made by the lamps burning in reverse order was their adaptation to decorative treatment.

When Professor Bunte addressed the Paris assembly the Welsbach light seemed to be the last word in illumination, and yet it was the dawn of an inconceivably greater illuminant — electricity. While electricity is superior to gas in one respect, it may be asserted confidently that gas will hold its own for some time with overworked housewives, who for the last decade have been relieved from the drudgery and uncertainty of the coal range.

*ONE of life's little ironies for the editor of a sheet like the* SCIENTIFIC AMERICAN *is the frequency with which he is asked to state name and date for an "invention" which in reality was not at all a single invention by one man, but came rather through a long series of experiments and semi-commercial developments by many men. If we name the first of these men as the inventor, we are immediately challenged to show just what he invented; if we name the last, we are driven into a corner and compelled to acknowledge his indebtedness to all his predecessors. With all this in mind, it was with considerable diffidence that we followed Mr. Andrews into his effort to establish 1920 as the centenary of gas lighting. But we believe all readers will agree that he has made out a passable case, and that he is entitled to say that the present year comes about as close as any year can to rounding out an even century of this style of illumination.*—THE EDITOR.

## Attractive Farm Signs

ONLY a few years ago the signs encountered in a farming district were all of clothiers, hardware houses, druggists, and other city stores, or of tobacco manufacturers, medicines for man and beast, baking powders, and the like. These varied interests saw an advertising opportunity in placarding the countryside with metal and wooden signs. But times have changed. The signs one now sees in growing number are more and more the farmer's own, designed to convert to his own use such advertising opportunity as exists.

Some of the signs are to advertise products for sale, the appeal being to the passing auto traffic. Another use of signs is to advertise the fact that the farmer is the member of the local farm bureau, and a supporter of its project. Some Western districts are using the farm sign, or are planning to, in a campaign to displace the scrub animal.

The other day a large California coöperative association, the Prune and Apricot Growers Association, placed a big order for baked enameled signs, in colors, to be posted on the orchards of members. This association will need over 10,000 to begin. These snappy, up-and-coming signs will help to maintain the prestige of the association at home, and incidentally will be a good advertisement to all visitors. The prune and apricot growers are not the first to use them—the raisen growers, the citrus growers, and the walnut growers already do.

Thus we see that the roadside sign is not disappearing, only changing in character. It becomes now a business device of the progressive farmer. And in this new use, ultimately, it is to be expected that it will lose the ugliness which formerly always was associated with it. The users of the old-time country metal sign were indifferent to its appearance, so long as it "advertised." Farmer-users won't long be.—By *J. T. Bartlett.*

# Tuning and Testing

## How the American Automobile Engine Is Limbered Up and Tested for Flaws

By George Gaulois

THE best grade of American manufactures of all kinds are today meeting severe tests with complete success. The higher quality of American watches excel the Swiss product at one-third the price. American machine tools lead, not only because of their ingenuity and cheapness, but because of their excellence. And American automobile engines, in spite of the glamor which with some people still hangs about the word "imported," are equally superior in spite of the far larger numbers produced and the far lower price.

In this story we are dealing with American automobile engines produced by the quantity production system.

Aside from the test which comes from actual experience, the best data can be obtained on the performance of any engine by an inspection conducted on the dynamometer. This method of testing is used to a greater or less extent in all the high grade automobile establishments in America. Its operation gives vivid example of the reasons for the superiority of the American engines.

In one leading plant, for instance, every engine turned out must pass the dynamometer tests. In spite of the most careful work in the manufacture of parts and most careful assembly, an engine, whether made by European or American processes, is so "stiff" that it is practically useless when completed. At that stage it is barely able to run itself and far less to propel a vehicle. The engine testing combines the functions of taking the stiffness out of an engine and that of reserving its quality to the most minute detail.

When the engine first comes from the assembly, it is put upon what is known as a "lapping-in stand," where it is driven by an electric motor until the internal resistance is reduced to a little above four horse-power. With the cheaper grades of engines, this "lapping-in" with a general inspection of the engine is all that is required and it then goes into the car. With the higher grade engine, the tests have merely begun at this point.

When a motor is taken from the "lapping-in stand" where it has been tested in thirty-six points, it is carried to the "silent rooms." These are completely enclosed so that no outside noises will prevent the detection of the most delicate fault in the engine. In this room is the dynamometer, which consists primarily of a generator mounted on bearings so that it may turn easily but attached to a scale so that it will not turn but the amount of torque will be measured accurately. Besides this, there is a tachometer which gives the number of revolutions that the engine under test is making per minute.

From these two instruments can be calculated exactly how much horse-power is being developed. If, for example, the scale shows a turning impulse of 111.1 pounds and the tachometer 2,000 revolutions, the formulæ show that the engine is developing seventy-four horse-power.

The other furniture of this room includes the switchboard, the jack for the motor and the pipe connections for oil, gasoline, water, etc. There are special instruments provided, including thermometer, compression clocks and a stethoscope.

The engine here is put through a series of 114 different tests. These cover the operation of the engine itself, of all its accessories, of the crankshaft assembly and of the transmission. In making them, the engine is run under its own power until it is thoroughly warmed up and the tests are then made under conditions which are almost exactly those of actual work.

The minor details of the engine are examined first, including the spark plugs, the valves and their timing, the ignition and feed system, the carburetor adjustment, and a general examination to make sure that there are no leaks in any of the water, gas or oil lines or in cylinder heads or crankcase.

The more important and delicate of the tests is made with the stethoscope, as shown in our current cover illustration. This differs from that used by a doctor only in the fact that it has a brass cone instead of a diaphragm disk. The point of this cone is moved over the motor inch by inch, and with it the tester can detect and locate noises which are entirely beyond the reach of the unaided ear. The use of the stethoscope is a comparatively recent development. In the old days, the tester hunted for these faint noises with a screw driver, holding the bit against the engine and the handle to the ear.

The noises which are detected in this way indicate trouble in embryo only There is no possibility that the buyer of an engine would detect them if the car were sent out without this inspection. But they all denote some weakness which might develop after the engine had run some thousands or tens of thousands of miles, and the pains taken to find and correct them gives insurance of long life and perfect performance by the engine.

If this test is made without trouble being detected, it has been made doubly certain that the engine is as near perfect as possible and far more perfect than nine out of ten of the best jobs that can be turned out by the hand-fitting process.

The test of the engine has not been completed, however. Following the stethoscope examination, the "power curve" is taken at 400 revolutions a minute, then at 500 and so on at every hundred up to 2,000. The engine is then set for 1,000 revolutions and there is another stethoscope diagnosis for troubles that may possibly have developed through the hard work done. Transmission and auxiliaries are then checked for noise, lost motion, amount of play and all other possible ills. No motor may be passed that suffers from what the instruction sheets describe as "vibration, knocks, growls, or rumble."

The engine is then tested for compression. A special gage is shoved into priming valves to try the compression of each cylinder separately. On this engine a difference of only five pounds in the compression of each of the twelve cylinders is permitted. If an engine

### The Finger Nail Phonograph

To the Editor of the SCIENTIFIC AMERICAN:

The following odd discovery in connection with phonographs may be of interest, and if published, may lead someone along new paths of inquiry:

If the nail on the forefinger of the right hand be slightly sharpened and filed, so that it will fit into the groove of a record while in motion, a faint reproduction of the record may be obtained. The sound is very minute, and the best method of hearing it is to lay the right ear against the hand. In this way the record can be clearly heard and the words of a song can be easily distinguished.

It would be interesting to know the reason for this peculiar phenomenon, and perhaps some anatomist or scientist may be able to supply a solution.

If a needle be held between two fingers no sound is heard.

Ottawa, Ont. R. E. SNEYD.

### Movie Science

To the Editor of the SCIENTIFIC AMERICAN:

The moving pictures are no whit behind the newspapers in the matter of highly original contributions to science. There was recently exhibited in this city a picture showing a diving bell, by means of which submarine photographs could be made. After showing the bell suspended slightly above the deck of a steamer, with the photographer crawling in under it, then being lowered into the water, the following illuminating explanation was flashed upon the screen.

"The diving bell has no bottom, the water being prevented from entering by the vacuum which is formed."

Surely that must have been a powerful vacuum! Hereafter, in order to prevent burglars from entering my house I shall remove the massive oak door and block up the doorway with an empty space. Sir Oliver Lodge tells us that the ether which fills all space, whether otherwise occupied or not, has a density of a thousand tons per cubic millimeter, and a tensile strength of $10^{22}$ tons per square millimeter. That ought to stop something.

Los Angeles, Cal. M. C. MOTT-SMITH.

### The Hudson River Crossing

To the Editor of the SCIENTIFIC AMERICAN:

I read with great interest in the latest edition of your most useful paper an article on the probable effect of CO in the tunnel to be built under the Hudson.

The true solution is a bridge over that river. While the best terminals for that bridge would be the Palisades and the hill at 10th Avenue and 62nd Street, the problem of foundations will have to govern the site of the bridge. I believe the Pennsylvania Railroad tunnels rest on caissons which in turn rest on bed rock, showing that in some parts of the Hudson caissons can be sent down to rock.

Permission for these foundations and piers must be obtained from the War Department and herein lies the real difficulty. To persuade that monument of conservatism to grant permission for such a great public improvement seems hopeless. However the attempt should be made. Only by an overwhelming public demand can anything be done.

On such subjects your journal is the most influential paper published and I hope you will make the attempt to start public opinion in the right direction.

New York. F. A. DE PEYSTER.

### Postponing Payment

To the Editor of the SCIENTIFIC AMERICAN:

Referring to your editorial on "Our Surplus, Our Ships and Europe's Need," I would inquire how these surplus commodities of a value of two billion four hundred million dollars are eventually to be paid for? This is the difficulty, for temporary means to finance the transaction are quite simple. The problem is, with reference to the payments in the future.

The ten billions which you say we have loaned Europe probably refers to the moneys loaned by the United States Government to the governments of Europe and as this money was spent in winning our war, there is some question as to whether it will ever be paid. But in addition, the countries of Europe owe to individuals in the United States about five billion dollars, and the interest on this debt must be paid, and unless the money is permanently invested in Europe, the principal must also be returned. If in addition to the five billions we add two billion four hundred million, it will mean that Europe must send to us in interest five hundred million dollars or more a year, and as there does not seem to be much chance of Europe shipping gold in such quantities, we must make still further investments in Europe, if we do not accept merchandise in payment of the interest. In other words, to the extent of this interest, our imports from Europe must exceed our exports. If the principal is to be paid and not invested abroad, the value of our imports over exports must be even greater. Should the interest be invested abroad, we will only postpone the day when we will be obliged to accept great quantities of merchandise as interest on our loans.

Tenafly, N. J. EVERARD B. MARSHALL.

### Use of Light for Reproducing Sounds

To the Editor of the SCIENTIFIC AMERICAN:

Referring to a note on page 402 of your issue of 16th October, I may say that the idea is *not* new, having been worked out in practical form 20 years ago and patented by Prof. Ernst Ruhmer (see his book on Wireless Telephones). I myself worked out the full details independently of him but went no further to popularize the matter when he took out his patents. About 5 years ago as his patents were expiring, I tried to interest a New York film manufacturer and he referred me to a talking machine manufacturer who referred me back, and as I had other things to do I had no time to go further.

I may add that in my own design I used what I think an improvement, viz., a semicylindrical lens to give the line image on the film. I had noted for experiment many points such as the use of heat rays and also the use of ultra-violet rays (for example as promoting discharge between terminals). Possibly, as the matter seems again arousing interest some note of a fuller character by you would interest the public.

# The Dawn of American Commercial Aviation

## Why We Have Trailed Behind Europe and How We Hope to Catch Up in the Near Future

By Ladislas d'Orcy, M. S. A. E.

*THERE is no use mincing words: the American aeronautical industry is decidedly at a low ebb. Following the Armistice and the suspending of heavy Government orders for airplanes of all kinds, our aircraft manufacturers found themselves with a large stock of raw materials and expensive plants, with little or nothing to do. In other words, we in America had nothing to take the place of wartime flying. Meanwhile, Europe forged ahead in commercial aviation. Although we were the first to introduce winged mail, Europe has eclipsed us beyond a doubt. And Europe has done remarkably well in commercial aviation. We are a considerable distance behind, true; but it is with some satisfaction that Americans at last can rest assured that a start has been made in American commercial aviation, and that a practical way has been found to make such ventures profitable. This is the story which we have asked Mr. d'Orcy, a well-known authority on American and foreign aviation, to tell our readers.*—THE EDITOR.

A SIGNIFICANT ceremony took place a few weeks ago at the Columbia Yacht Club, on the Hudson, in New York City, when Rear Admiral Glennon, commander of the Third Naval District, raised the American flag on two large Aeromarine flying boats constructed for a daily mail and passenger service between Key West and Havana. This act truly marks, as Charles F. Redden, president of the Aeromarine Engineering and Sales Company, remarked in his inaugural speech, "The first constructive step in the history of American rapid transportation toward the creation of regular passenger air lines such as are operating in Europe with marked success."

Although the first country to start the operation, in May, 1918, of regular air mail services, the United States was later outstripped in commercial aviation by England and France, in which countries numerous passenger air lines have been organized since the armistice. America's tardiness in taking advantage of the latest means of rapid transportation may in part be justified by the fact that while the British and French Governments accord various kinds of direct or indirect financial assistance, until recently nothing of the sort was forthcoming from our own Government. Lately, however, the Post Office Department decided to supplement its own air mail routes by letting out contracts for the carrying of mail by privately owned aircraft.

This commendable policy affords air transport firms just the kind of indirect financial assistance they require for making commercial air service a sound business proposition, and the organization of the Key West to Havana air line is its first practical result.

It may be asked why air transport companies should require government assistance. The reply is that the organization of "airways"—as commercial air services are now referred to—demands a considerable capital outlay, firstly, because of the extensive "ground organization" required, and secondly, because at the present time airways can be made commercially sound only if a certain amount of pay load is guaranteed. Just as the merchant marine could not operate its ships without adequate harbor facilities, no airway can be run without airports, emergency fields, fuel depots, repair shops, aerological and radio stations, etc. Now all this ground organization hardly exists in this country, whereas in Europe the governments have undertaken this work as a matter of public utility.

On the other hand, the problematic nature of the pay load is due to the fact that the "aerial traveler" represents an economical factor that has yet to be created.

This is what the Aeromarine West Indies Airways set out to do when they decided to carry passengers in addition to the 500 pounds of mail they are under contract to transport daily between Key West and Havana. The service is operating with a fleet of six twin-engine flying boats, three of which bear the names of Columbus' caravels—"Santa Maria," "Pinta," and "Niña." This type of commercial seaplane was developed by the Aeromarine Plane and Motor Company of Keyport, N. J., from the famous "F-5-L" class of naval aircraft which the United States Navy produced during the war in response to the German submarine menace. Owing to their large carrying capacity and reliability, these flying boats were able to carry important loads of bombs over great distances and thus became largely instrumental in clearing the Allied sea lanes from enemy underwater craft. Since the armistice an "F-5-L" seaplane established a new world's endurance record by remaining in the air without alighting for twenty-four hours and nineteen minutes—a performance which will give the reader an idea of the possibilities of these machines.

The reconstruction of the "F-5-L" type into a mail and passenger carrier consisted mainly in reducing the fuel capacity from ten to four hours and in equipping the hull with two comfortable cabins seating six and five passengers, respectively. The cabins are situated one forward and one aft of the wings and are furnished with comfortably upholstered reclining chairs from which the passengers can gaze upon the underlying panorama through regular portholes fitted with curtains. Altogether the accommodations are fully comparable with those one expects to find on a large sized motor boat or in a limousine. A passageway inter-connects the cabins, which are reached from the deck through two hatches. A sliding door furthermore allows direct access to the after cabin.

Amidships, and raised over the roof of the cabins, is situated the contral cockpit, which can accommodate a crew of four men and holds a dual control set, the necessary instruments, and a radio outfit with a two-way range of 50 miles.

The weight of such a flying boat, fully equipped and including the water for the radiators (226 pounds) and emergency provisions, but excluding fuel, oil, crew and pay load is apportioned as follows:

| | Pounds |
|---|---|
| Hull and fittings | 2,340 |
| Wing and tail structure | 2,613 |
| Machinery | 3,136 |
| Navigational | 150 |
| Radio | 160 |
| Electrical | 57 |
| Total | 367 |
| Total net weight | 8,456 |

## A Canoe That Travels Over Roads

AT the recent canoe regatta held in Grunau, Germany, not so long ago, the canoe-automobile shown in the accompanying illustration attracted no little attention. This machine is nothing more than a standard canoe mounted on light automobile chassis. Holes have been cut out of the bottom of the canoe in order to bring through the steering post and dashboard connections. The emergency brake and the gear-shift levers have been left outside, in accordance with the standard European practice. All in all, this may be called a canoe which travels over roads, for it is still a canoe so far as shape and seating arrangements are concerned.

**These German watermen have mounted a canoe on a light automobile chassis**

## Glass Windows for the Salvage Pontoon

DAY by day we learn of something new in the way of salvaging equipment and methods. And naturally enough, for never has there been so fruitful a field for the imaginative mind and the inventive genius as at present, when the seas are liberally dotted with wrecks which await the operations of enterprising salvagers.

From Denmark comes the accompanying view, showing a pair of aluminum pontoons equipped with glass windows. An interior chamber runs the entire length of these cylindrical pontoons, which are pointed at each end. A portion of each pontoon is provided with stout planes of glass, which, presumably, are of sufficient strength to resist the heavy pressures brought to bear on them by water at even small depths. The occupants of these pontoons are provided with powerful electric lights so that they can see the progress of the work under water, and direct the divers in attaching hawsers and doing other tasks. The lifting power of the pontoons, which must be considerable, is also depended on for raising the sunken object.

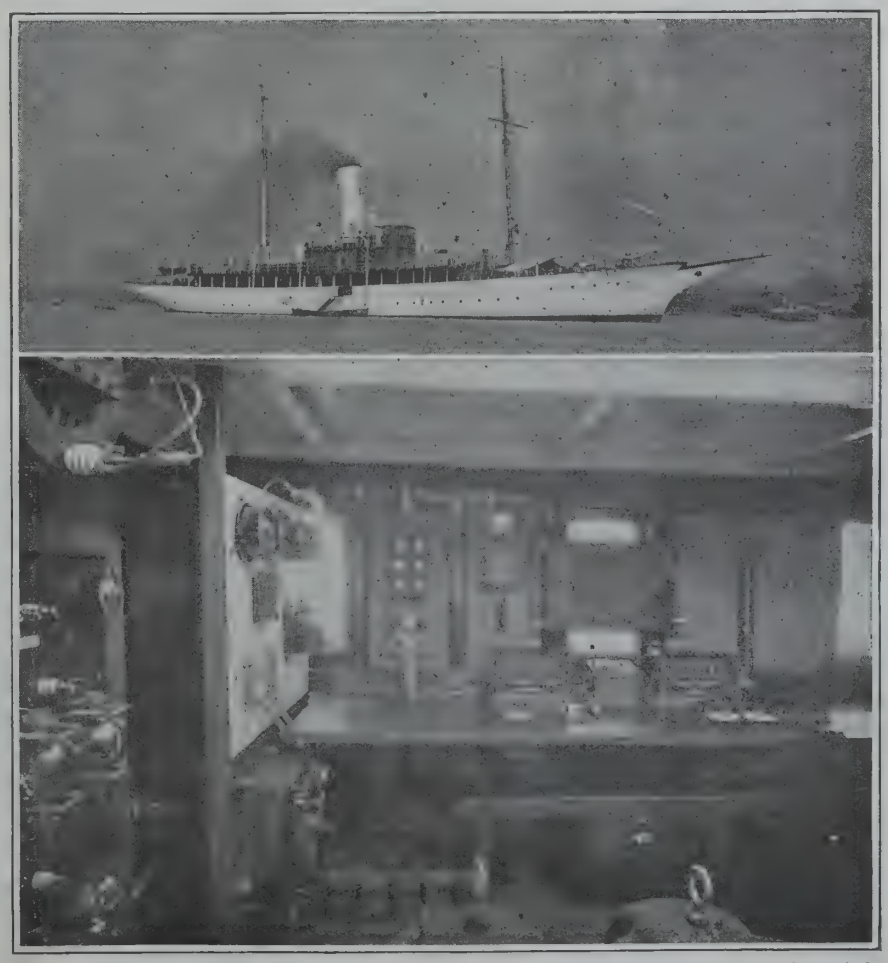
**Glass-sided pontoons that have been constructed in Copenhagen Harber for certain salvaging operations**

## Marconi's Floating Laboratory

MARCONI, as a great inventor, runs true to form: he is indefatigable in his researches and improvements and new ideas with regard to radio communication. Not content with having laid the foundation for practical wireless telegraphy, he has continued year by year in the marvelous development of radio communication.

In this connection the yacht "Electra" is of cardinal interest, for it is aboard this private vessel that Marconi does much of his research work. Our two views show the yacht and the wireless laboratory aboard it. A vacuum tube transmitter for undamped wave transmission, suitable for radio telegraph and telephone messages, appears at the extreme left, followed by a power switchboard. The long table contains vacuum-tube receiving and amplifying apparatus, as well as delicate instruments for making quantitative tests of the received signals. In the center foreground may be noted the very tops of a motor-generator set.

We have it from British sources that Marconi has recently been experimenting with radio transmission and reception of extremely short waves, which can be reflected by means of special reflectors in very much the same manner as light waves. The famous inventor is said to be experimenting with a view to using these short radio waves in foggy weather, when one ship can detect the presence of another ship by picking up these short waves and getting the direction of their source. The receiving device will be in the nature of a rotating mirror, which will stop when radio waves strike it head on, thus giving the direction.



**The steam yacht "Electra" and Signor Marconi's radio laboratory aboard it**

## Utilization of Refuse Slate

RECENT developments in the recovery and utilization of waste slate have led to the extension of processes for the production of paints, distempers, putty, brick, blocks, slabs, tiles, mortar, plaster, flooring, rubber, and molded goods. A firm in North Wales now claims to be able to build and decorate a house with slate waste, with the exception of woodwork, glazing, ironmongery, and plumbing. An article which appeared in a recent issue of the *Stone Trades Journal* contained the following particulars:

To find a use for the slate waste of the quarries is a problem that has occupied the minds of those interested in the slate industry since slate superseded tiles as the roofing material, which is upward of 300 years ago; but at no time has this subject been of so much importance as it is likely to be in the very near future. The slate trade is at present booming, but the boom is not likely to be everlasting. When things slacken in the building industry and when foreign competition has again to be met, prices are likely to drop from their present high level, and an outlet for the waste of the quarries would go far to assist the owners to stand the reduction. It has also to be borne in mind that the rock in many of the important quarries is deteriorating; this is a very serious matter for the quarry owner, and has increased the cost of working considerably.

At different periods efforts have been made to utilize the waste. It has been tried as a road-making material, but was not a success, roads made with slate being very dirty in wet weather. However, there seems to be no reason why it should not be used as a binder in the form of chippings, of which there is a scarcity in the country and for which there is a ready sale at a fair price. It should make a good binder for granite macadam, either tarred or untarred. It has already been tried in brickmaking and is again having a trial as such. A test made some time ago for strength and absorption between a brick made with slate dust and one of the best blue bricks showed the slate brick to be the stronger and exactly equal to the blue brick in absorption of water. Price was the consideration which killed the possibility of making slate bricks before, but at present this should not be the case.

An attempt was also made to find a market for the waste in the form of drain-pipes, and some of the pipes may yet be seen which had as their foundation slate dust. In the manufacture of cement it is claimed slate dust is excellent; and in the slate-quarrying districts a mastic made of slate dust and oil has frequently been used for leaky roofs, the mastic when set being harder than the natural slate.

The endeavor of a North Wales company to work the slate-dust business in the Bethesda district on a large scale is fairly well known in the trade, and its experiment is being watched with interest and copied on a smaller scale by a few. There is a very big demand for slate dust ground to a fine powder, and if it can be so ground at a reasonable cost there is every prospect of the business developing considerably.

## An Apple Warehouse of Hay

A SERIOUS shortage of cars, in combination with the biggest apple crop the Pacific Northwest ever had produced, led to an acute situation in Oregon and Washington last fall as the season of frost danger approached. With applies worth well over $2 a box, storage became a very serious problem.

Various makeshifts were resorted to. Church basements were filled with apples, while other church buildings not in use were filled to the roofs. Unoccupied business premises in the apple towns were hired for storing purposes. But perhaps the most interesting device was adopted by a resourceful apple grower at Omak, Washington, who couldn't get cars in which to ship his apples and simply had to devise some kind of efficient storage or suffer a heavy loss.

In his dilemma he remembered that hay has high insulating quality, and that in the baled form it lends itself readily to manipulation. He bought 150 tons of hay, and with it constructed the four walls of a warehouse. On top he put a roof of more prosaic materials. Into this his boxed apples were placed.

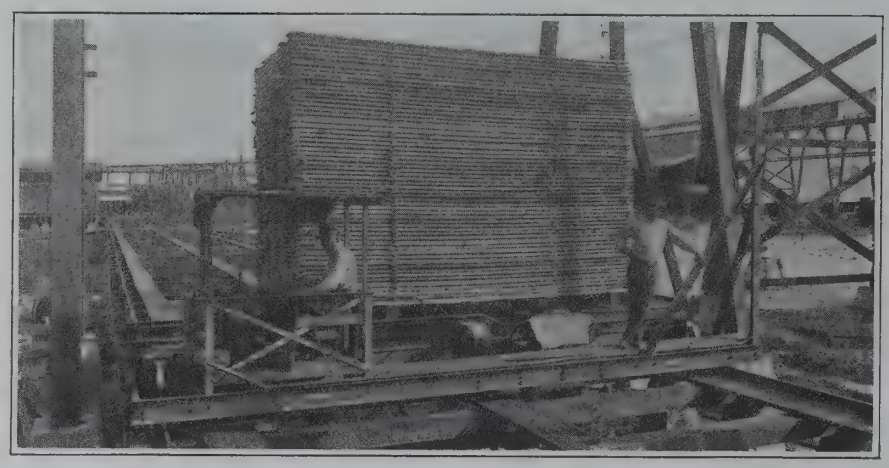
The ingenious apple man declares that his hay warehouse has answered the purpose in every respect.

# In the Modern Sawmill

## Machines and Methods by Which the Cutting Up of Logs Is Put on a Basis of Extreme Economy

By Harry A. Mount

WHERE is the man who, standing in a great modern sawmill and watching the panorama before him, has not marveled at the ease and facility with which a giant of the forests is converted into the lumber of commerce? There is something genuinely fascinating about the crash and whir of the great saw as it slashes through a mighty tree trunk with unbelievable swiftness. And in the whole lumber industry, not excepting the woodsman himself, there is no more picturesque figure than the head sawyer as he rides back and forth on the log carriage past the whirling saw, controlling this mighty display of power by a movement of his hand.



An electric transfer table with load of lumber

A visitor at a modern mill will not fail to be impressed, too, with the small number of employees required to turn out hundreds of thousands of feet of lumber a day and with the economy that everywhere is evident. It is said that the meat packer finds use for every part of the pig except the squeal. The pig is lucky compared with the log that passes through this mill, for even the sawdust and scraps are burned under the boilers which generate power.

The most surprised visitor of all, no doubt, would be the man who is familiar with the sawmills of ten years ago. The demand for timber has grown apace in the past few years and the lumber industry has made rapid strides in the improvement of its production methods.

In the early days the power employed was that of oxen or horses, or water from a nearby stream. A familiar sight near a lumber mill was a yoke of oxen dragging a load of logs to the saw. Later the ox and horse were superseded by the power of the steam engine. Today the largest and most modern mills of our Pacific slope and in the Southern pine belt, are electrified, and instead of the maze of belts and shafting, a few small wires enclosed in iron pipes, carry the power needed to cut up the big logs. How much this has added to efficiency may be judged from the fact that the electrification of one Southern sawmill recently resulted in a 20 per cent increase in output without the addition of a single machine or employee.

As an example of the amount of power required, one mill on the Pacific Coast which has a capacity of 500,000 feet a day, uses over 350 electric motors totaling in excess of 6,000 horse-power.

Transportation is undoubtedly the most important single factor in lumber production for the lumber must be carried from the lumber camps to the mills, from one machine to another and finally must be carried away from the mill. It is interesting to note that in the case cited above about 75 per cent of the installed capacity in motors is used for purposes of transportation. A trip through this mill will give a general idea of a modern sawmill.

The lumber is floated to the mill from the logging camps, several miles away, by river. The logs are pulled from the water by cables, attached to electric winches and are piled on an unloading dock. As needed in the mill they are rolled into a steel trough, at the bottom of which runs an endless "bull chain." Spaced every few feet are steel hooks or "dogs" which grip the log and carry it along and up an incline into the mill. As the log passes up the incline it goes through a shower bath of high pressure water, shot at it from all sides to remove dirt and stones, which might injure the saws.

At the top of this incline the logs are "kicked" off the conveyor by pneumatic arms and roll on to an incline, down which they slide by gravity into the log carriage. This carriage shuttles back and forth past the "head saw" or main saw and at each trip a big slab of the log is sliced off.

The head saw deserves special attention. Instead of the enormous steel disk that we might expect, we see a huge band saw. The saw blade is about a foot wide and it passes over large wheels, one overhead and the other beneath the floor. Although we cannot see, it is driven from beneath by a great electric motor of 250 horse-power, but there is evidence of resistless power in the businesslike snarl of the saw as it eats its way rapidly through huge logs.

Just in front of the "head saw" is a smaller circular saw, which merely cuts a slot through the bark. It is called the "rock saw" and its function is to dig out imbedded rocks from the bark which might otherwise do serious damage to the expensive head saw. Pipes from a motor-driven blower carry the sawdust away, unseen, to the fuel bin.

As the slab from the log falls off, it alights on a chain of "live rolls" or motor-driven rollers, which carry it away and deliver it to the "edger" where, at the will of the operator, the slab is transferred to the machine by means of trip skids. These skids are raised by a cylinder, the valve of which is operated by an electromagnet and push button within easy reach of the operator.

The "edger" consists of an arbor on which is mounted two circular saws and as the slab is pushed through these it is sawed to the desired width. The slabs may go, instead, to a "slasher," which consists of an arbor on which any number of saws may be mounted, and upon being forced through them the slab is sawed into any number of boards. The log may be sawed into planks by these machines and these planks sent to the gang saw. This consists of a number of straight saws with a vertical reciprocating and oscillating motion, which split the plank into boards of the desired thickness.

Some of the boards pass through trimmers and others go to a resaw machine to be brought to the proper thickness. A system of live rolls does all the transferring from machine to machine and at strategic points are located "jump" or "swing" saws for cutting the boards to proper lengths.

The lumber all finally comes to a "sorting table," where by a rather complicated arrangement of rolls and chain conveyors, the lumber is sorted. From the sorting table the lumber is taken by transfer cars to automatic stackers, and thence to the dry kilns. From the kilns the lumber goes to the yards, where electric trucks and tractors, transfer cars, and

1. Yield of potatoes in fields over which the air was fertilized with carbonic acid gas and left unfertilized. 2. A similar comparison for cauliflower plants. 3. An open-air carbonic-acid fertilizing plant

**Fertilizing the air with carbon dioxide to promote plant growth**

## Carbonic Acid Gas to Fertilize the Air

**By Dr. Alfred Gradenwitz**

ONE of the principal constituents making up the body of a plant is carbon, representing about one-half of its organic substance. The opinion that this carbon is derived from the soil has long been abandoned, modern investigation having shown atmospheric carbonic acid to be absorbed by means of the chlorophyl or green matter of the leaves and decomposed into its elements, the carbon, in conjunction with the root sap and atmospheric moisture, being worked into organic compounds.

Whereas atmospheric air at present is relatively poor in carbonic acid, of which it contains only about .03 per cent, at an early period in the development of our planet, when this was covered with the luxuriant forests our coal deposits are derived from, it comprised incomparably greater quantities of this gas. This fact suggested the idea of heightening the fertility of the soil by increasing its carbonic acid content and thus producing conditions resembling those of antediluvian ages. In order to enable such a process to be carried out on anything like a commercial line, a cheap source of carbonic acid had, of course, to be provided.

This was found by Dr. Fr. Riedel of Essen-on-Ruhr in the combustion gases escaping from all factories, but most abundantly from blast-furnaces, and which so far had been allowed to flow out into the atmosphere without serving any useful purpose. He accordingly set to work designing a process for which patents were obtained and which was put to practical tests on a large scale. Three greenhouses were at first erected, one of which served as testing room, while the two others were used for checking purposes. The testing room was supplied with purified and burnt blast-furnace exhaust gases through a line of punctured piping traversing the whole greenhouse in a forward and backward direction. The gas supply was started on June 12th, that is to say, at a time when plant growth was at its height.

On account of the careful cleansing and complete elimination of constituents such as sulfur, the gas was found to exert no harmful effects. On the contrary, even a few days after starting the test, there could be observed in the testing room a more luxuriant vegetation than in the checking houses. The leaves of the castor-oil plant in the greenhouse supplied with gas were found to reach more than one meter in span, whereas the largest leaf in the checking houses was only about 58 centimeters in width. Plants submitted to the influence of carbonic acid gas also showed a marked advance with regard to their height. With the tomatoes planted in another part of the greenhouse a crop of 29.5 kilograms was obtained for a given number of fruits, the weight of the same number of fruits in the testing room being 81.3 kilograms, that is, 175 per cent more. With the cucumbers planted at the same time a somewhat slighter difference was noted, the yield in the checking houses being 138 kilograms, in the testing house, however, 235 kilograms, corresponding to an increase in yield of 70 per cent. An interesting phenomenon noted in this connection was that, while the cucumbers in the checking houses would exhibit bright spots, those in the testing house, on account of the more plentiful formation of chlorophyl were of a dark green color throughout.

Experiments in the open air were made simultaneously with these greenhouse tests, a square plot of ground being encircled by punctured cement pipes from which a continuous supply of exhaust gases was escaping. The wind, mostly striking the ground at an angle, would drive the carbonic acid in a variable direction

(*Continued on page 557*)

## Mechanical Stevedore That Handles Bananas

**By Thomas Ewing Dabney**

A NEW application of an old principle—which is all that invention is—has met the high cost and scarcity of labor on the wharves of New Orleans, and enabled that port to expand its trade in its most important article of import—namely, bananas. This is a handling device which transfers the fruit from shipside to the cars at an estimated saving of 2½ cents a bunch. As New Orleans imports 20,000,000 bunches of bananas a year, this means a gross saving of $500,000. Add to this the saving in time and the fact that there is less damage to the fruit by the mechanical than there is by the physical method of handling, and the annual saving will not greatly miss the million mark.

About 600 shiploads of bananas are brought to New Orleans a year. The average ship carries 35,000 bunches, which are under present conditions unloaded in about seven hours. Three machines of the type shown in the SCIENTIFIC AMERICAN of Oct. 20, 1917, lift the bananas out of the ship and deposit them on the wharf. These machines consist of 50-foot structural towers, with a base 14 by 28 feet, set upon eight wheels resting upon two transverse rails at 14-foot gage. This tower is fitted with a main boom and a plumb marine leg which reaches into the hold of a ship; the bananas are lifted out in a continuous belt of pockets held between two parallel link chains which traverse the marine leg, main boom, auxiliary boom and tower, at the rate of 125 feet a minute. The bananas are finally deposited at the foot of the tower and then lifted upon the back of laborers, who carry them to the car a couple of hundred feet away. But the bus is too fast for the stevedores. Even with 1,000 men working, the greatest number that can be economically employed on the wharves, it is not possible for the machines to work more than 40 minutes in each hour.

To avoid this 33 per cent loss in time—and because of the rapidity with which bananas ripen, especially in the summer, every minute is worth money—William Steckler, an engineer of the Board of Port Commissioners of Louisiana, set his inventive brains in motion. He studied the trolley systems by which meat, auto tires, machinery, etc., are handled in manufacturing plants, and worked out a mechanical means of conveying the bananas from shipside, after they have been delivered on the wharf by the elevator, to the cars.

He has tried it out and it has proven a success. Every banana wharf in New Orleans is to be equipped with the device as soon as it can be manufactured.

The essential features of the device are an overhead monorail of medium design,

(*Continued on page 557*)

The bananas, hung to trolleys on a monorail, are pushed forward in the desired direction, by fingers attached to the chain shown near the top of this illustration, near L-1. The system is so devised that the over-ripe bananas are given separate and speedier handling There are monorail sidings, like ordinary railroad sidings, on which the fruit is stored until it can be put aboard a car

**A corner of the banana conveyor mechanism installed at New Orleans**

# With the Engineers of Industry

*A Department Devoted to the Physical Problems of the Plant Executive*

## The Sectional Unit Factory

HOW large is a building? This question, in just this form, sounds trivial enough; but if we translate it into somewhat different terms, and ask, with the executive, "How large a building will this department require, and how large a building can be erected for it in the time and with the funds available?" it takes on an aspect of real importance. One of the most embarrassing situations in all industry revolves about this problem of factory housing. And the statement that a new type of factory construction has been developed that automatically solves the problem before it arises is of interest to every growing business.

The principle employed is that of the sectional bookcase. We all remember what a task it was to house a growing library in the old days of the rigid bookcase, and what a boon we found in the bookcase that grows with the books, and is always just the right size to hold the volumes which we have to put in it. From the designer's viewpoint, there was little to the sectional bookcase save the idea. When that idea is taken over by the manufacturer of building materials, however, the idea becomes the least perplexing detail, and a great deal of careful thought must be devoted to the working out of styles and sizes of the building units, and to the means of joining them up.

The manufacturer who features this style of construction in his catalog uses pressed steel as his basic material. The design of each part has been carefully studied in order to develop maximum strength from minimum material, and of course maximum standardization. The wall unit, furnishing the starting point, is made in various heights, and is interchangeable with door units; it is furnished with and without window frames, so that by appropriate alternation any desired arrangement of blank wall or window space can be obtained. Every field joint and connection is made weather-tight and element-proof. Through the use of a simple and practical device which makes all field connections, the buildings are erected speedily and at a low labor cost. Since they can be taken down and re-erected without replacement of any part, they have a salvage value of one hundred per cent. The removal of one of these buildings, in fact, is a process entirely analogous to the taking down of a sectional bookcase on moving day and its re-assembling in the new apartment.

The length and width of the building may be carried to any desired extreme

(*Continued on page 558*)

## The Question of Reflecting Surfaces

OF fifty-eight large steamship piers which have been inspected, 42.6 per cent had illumination which was entirely inadequate and generally poor, 51.2 per cent had fair illumination and only 6.2 per cent had good illumination. The average watts per square foot of these electrically lighted piers was 0.16, varying from a minimum of 0.05 watt to a maximum of 0.34 watt. Very much better illumination results would have been obtained in nearly every case had the equipment been well maintained and the surroundings occasionally painted with white or other light paint. Only 3.6 per cent of the piers had white walls and ceilings; 9.1 per cent light-colored surroundings, 20 per cent medium-colored, 52.8 per cent dark, and 14.5 per cent very dark, almost black, according to A. L. Powell (Lighting Service Department of the Edison Lamp Works of the General Electric Company), an authority on illumination.

The results of the better conditions in those piers having well-maintained fixtures, light surroundings and adequate illumination were (a) greater actual speed of trucking, (b) markings more easily read, (c) fewer missent shipments, (d) spoilage and theft reduced, and (e) relations with the public greatly improved.

Of course, this particular survey deals with piers, but is it any different in the average factory? Black or dark walls mean the absorption of useful light which might otherwise be turned to some real work. There are many suitable paints on the market with highly reflective qualities which serve to distribute both daylight and artificial light into every corner of a large plant. There are numerous styles of fixtures which make for the maximum illuminating efficiency. But all these are of little use if permitted to discolor or become heavily coated with dust, since their efficiency is reduced in direct proportion to their departure from absolute cleanliness.

## The Matter of Steam Pipe Insulation

NO engineer would think of using bare wires for carrying heavy electric currents: he would insist on their insulation. Yet there are cases almost without end where plants which are held up as models of efficiency, use steam pipes that are not insulated in the proper manner. And just as electric current would leak in the instance of uninsulated wires, so do heat and steam leak or become weaker when carried through uninsulated pipes.

There is no excuse for uninsulated steam pipes at this time when, on the one hand, coal is selling at exceptionally high prices, and when, on the other hand, fuel engineers have made such a thorough study of heat insulation. Two symptoms, we are told by heat insulation engineers, always signal heat loss from a steam pipe. One is lowered pressure in the pipe, the other is high temperature of the air surrounding the bare or poorly insulated pipe. Obviously, this falling pressure or surrounding heat means that fuel in the form of heat is being wasted. Pipe insulation is necessary.

An insulation to be of maximum value must have more than the property of preventing heat loss. It must also have physical durability, for a short-life material means early replacement, so that if insulation values are equal, the most durable insulation is the most economical. A number of heat insulating materials are now on the market, and companies producing these materials have a staff of engineers who specialize in problems of this kind. Both indoor and outdoor installations, overhead and underground, and every other condition can be met by consulting the heat-insulating engineers.

## Spraying Paint for the Sake of Morale

AS someone has aptly put it, what a big difference the proper application of a little paint makes. Light, cheery, sanitary and thoroughly protected factory walls and ceilings benefit both plant owner and his men to an immeasurable extent. That is a different angle to the paint problem already covered in another item in this department.

But the accompanying big paint and labor bills, where costly, deficient painting methods are employed, are out of all proportion to the benefits derived. Again, in most plants the paint does not remain clean and fresh for any length of time, hence painting must be done at regular intervals.

Just here is where spray comes into its own. Any one of the several types of portable painting equipments now available makes possible four or five times faster work than can be done with the old-style paint brush. All coats are applied more thoroughly and uniformly on every part of the surface, insuring a longer wearing and greater light reflecting surface. The need of scaffolding is saved in many places. The men are enabled to work with less fatigue and to leave the surroundings in cleaner condition. The outside and inside work is done equally well with any kind of paint, requiring no more than when brushing. But why go on? The spray method of painting is unquestionably a vast improvement over hand method for such work as we have been discussing.

## A Rival of the Steam Whistle

IT may be that the steam whistle in time will be a matter of past history; at least, the steam whistle is steadily losing ground in favor of the electric siren, which has proved considerably more efficient in more ways than one.

In industries large and small, in mines, factories, foundries—wherever a warning signal with greater range and more distinction in tone than the steam whistle is required—the electric siren has been found to fill a long felt need. The electric siren is clear, unmistakable, most distinctive. It cannot be confused with any other sound. While a boiler full of steam is needed for the steam whistle, the electric siren may be operated from any number of places through the factory by a simple turn of the switch. It is always ready, dependable, fool-proof, insignificant in upkeep cost. The electric siren can be either large or small—large enough for the largest works, and small enough for use in any department of such works, where it must signal through the noise and din of incessant toil and bustling activity.

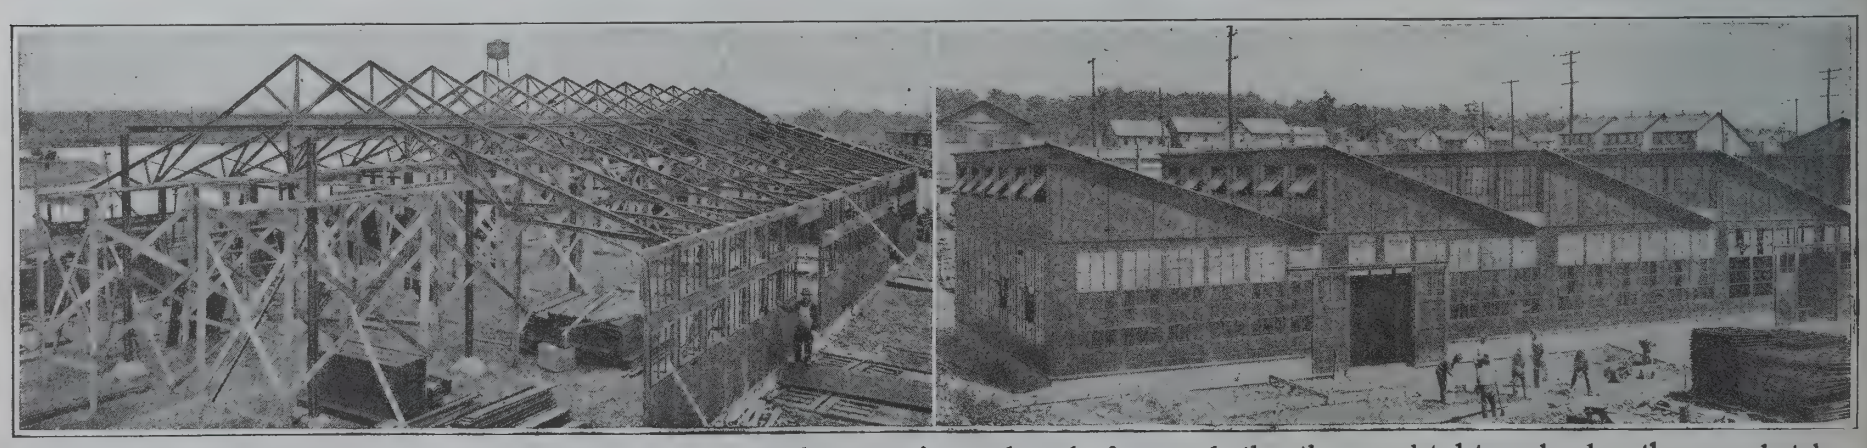
## A New Idea in Factory Heating

THE very expansiveness of the average plant often renders the usual systems of heating somewhat faulty and inadequate. The heat is not distributed through the large bays, because there is no way of getting it into circulation.

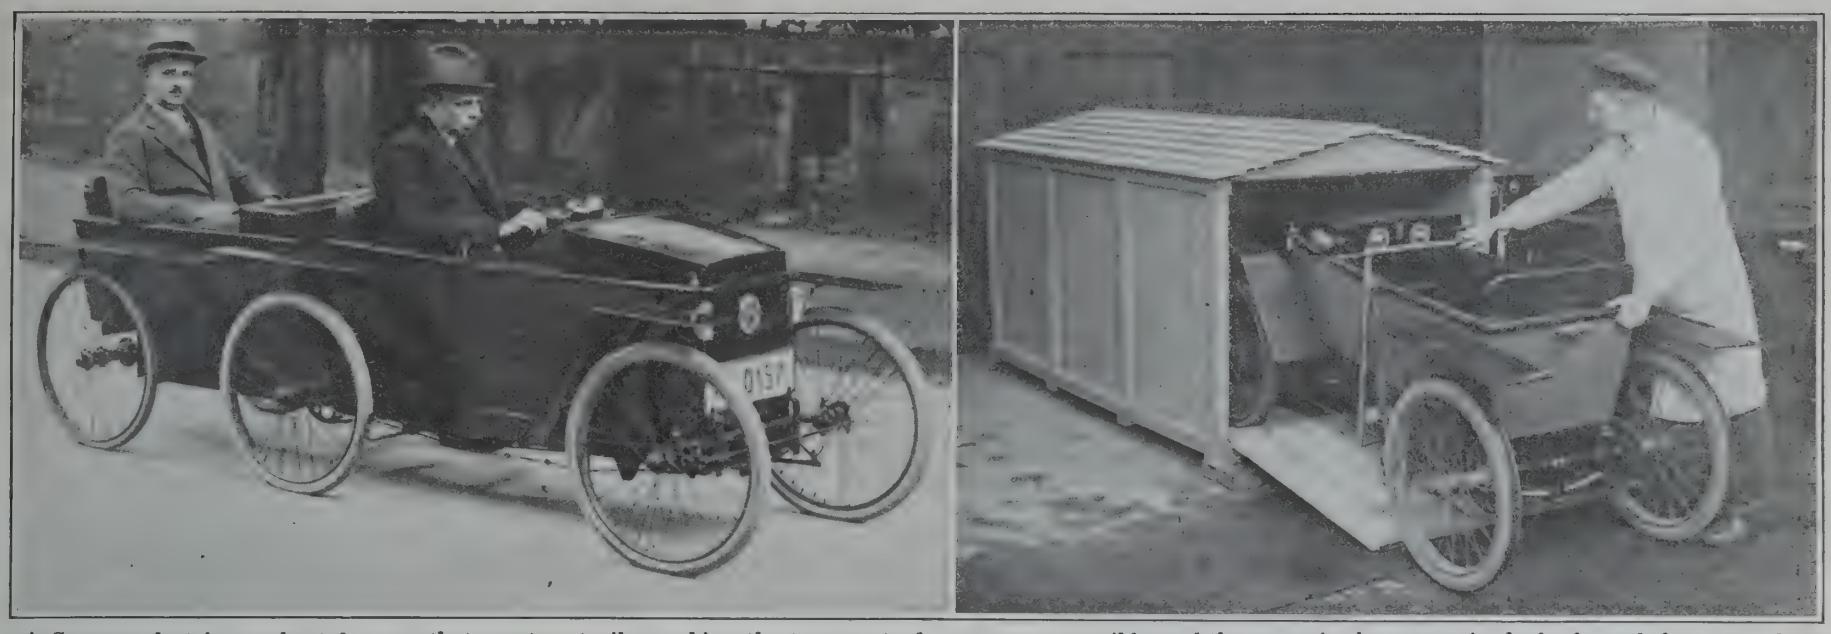
With a view to getting heat to every part of the largest factory bay, one concern has developed a heating system which is claimed to heat the factory to the same comfortable, uniform degree. No matter what the weather conditions, type of building, construction, size of space to be heated, and other factors, the new heating system is said to heat all of the open space, so that remote, far-off corners will be equally as warm as the area immediately surrounding the heater.

To get down to specific details, the heater is a compact, self-contained unit which requires no pipes or ducts for air distribution. Installation cost is 15 to 50 per cent less than other types and

(*Continued on page 558*)



**Sectional factory buildings of pressed steel units, one in course of construction to show the framework, the other completed to make clear the general style. In the latter, the individual units can be easily identified, and give some idea of the flexibility of this construction**



**A German electric runabout for one, that sports a trailer making the transport of a passenger possible, and that occupies less space in the back yard than some dogs**

## The Electric "Klein-Automobil"

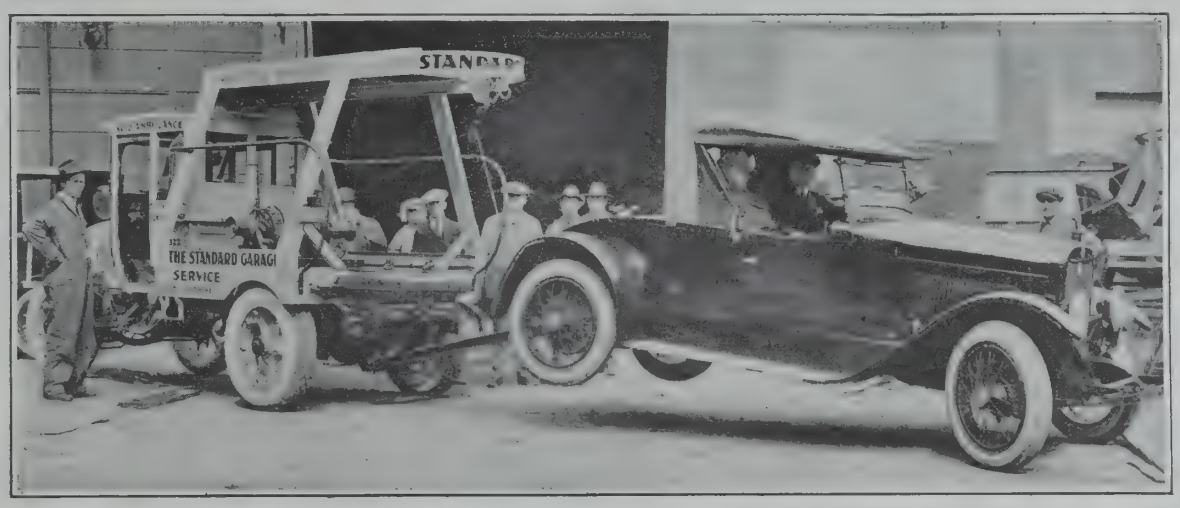
ON a recent motor trip between New York and Delaware Water Gap, we pronounced the main street of the largest town between Morristown and the Delaware to be the worst bit of road we had ever met; and we have heard of cars wrecked by the rough going on the Liberty Highway between New York and New Brunswick. When such things as this are possible, it is evident that the "small car" of song and story is the smallest and lightest vehicle that we can hope to employ on American roads for many years.

In Europe, on the other hand, road conditions are very different. There are literally thousands of miles of highway, fairly honeycombing Britain and the western part of the Continent, on which anything heavy enough to give itself traction will ride with speed and smoothness. Hence there is a large field for something that shall really be a little below the class of the true automobile—something that shall weigh a fraction of a ton only and make anywhere from 60 miles upward on a gallon of fuel. The existence of this field is daily attested by evidence both of production of such vehicles and of demand for them.

It now appears that the manufacture of these little runabouts is not to be confined to the gasoline system of propulsion. One of these tiny baskets on wheels, now being marketed by a German company, derives its power from batteries. The car is made in one model only, a one-passenger runabout, with wheel-base 57.12 and tread 33.45 inches. The weight is 440 pounds, which makes the suggestion of our picture, that the proprietor is picking his car up and tucking it away in its minute garage, not quite so absurd after all. To it can be attached the two-wheeled trailer for an additional passenger shown in our other view; or for this may be substituted an auxiliary of different style for delivery purposes.

Electric current is furnished by two 24-volt lead-plate batteries of 6 cells each, located in the forward part of the car. These require 2½ kilowatt hours for a full charge, which will drive the car about 35 miles in Berlin, where the streets are well paved and have fewer grades than in the average city. The electric motor develops about 1½ horse-power and permits a maximum speed of approximately 13 miles an hour. The motor is set well back in the frame, very close to the rear axle. The power is transmitted by a chain to a jack shaft set forward of the motor, and thence by a single chain to the right rear wheel. This use of a single driving wheel obviates the necessity of a differential.

The car is quoted at 13,000-14,000 marks and the trailer at about 4,000 marks. If it is not wholly clear that these are one-cent marks of the vintage of 1920, the quotation of 2,550 marks for a reserve battery ought to make it plain that this is the case, and that anyone who is in a position to apply real money to the purchase of this vehicle will get it very cheap. We are informed that the company has a present capacity of 100 cars per month, and that already 300 of the vehicles have been delivered and put into use.



**If the damaged car can be salvaged, this wrecking outfit will do the trick**

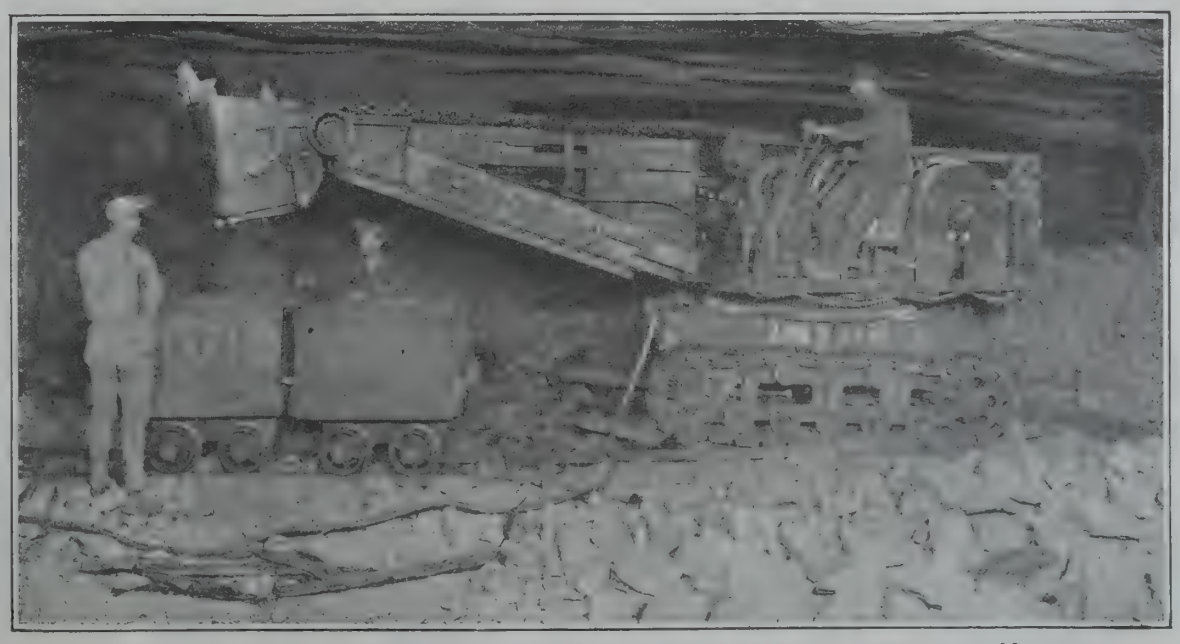
## First Aid For the Crippled Car

WE illustrate an admirable automobile ambulance which is in service at a Toledo garage, and which is of such evident all-around utility that it is difficult to imagine any case of a sick car which it could not treat — barring, of course, that the patient were totally defunct. The designation "automobile ambulance" is one given the new outfit on the basis of its performance, and one which it readily can be seen to deserve. Not at all cumbersome itself—its foundation is a 1½-ton chassis—it is able, with one man at the winch, to lift easily cars weighing in the neighborhood of five tons. Another feature of material value is the ability to pick up a car from the rear without damage to fenders, tank or body. This has always been difficult when a rear wheel or axle was damaged and the crippled car had to be moved to shelter.

## A Lilliputian Mining Machine

WHEN labor costs at a Missouri lead mine reached a point that made it necessary to consider the designing of a machine that would combine the digging and loading functions and that would not exceed 7½ feet clearance, it might have been supposed that this problem had no solution. A Lorain, Ohio, company undertook the construction of such a machine, however.

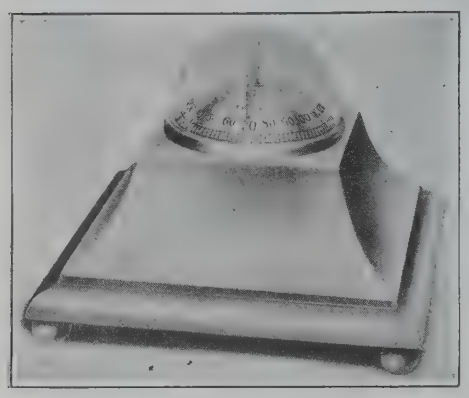
The machine consists of a rotating turntable which carries all the mechanism, and upon which is mounted the boom structure. The whole is carried by a truck frame operating on caterpillar treads. The machine is capable of digging and loading at any point in the circle. It is self-propelled and power-steered, so that it can be readily moved about in the mine. Provision is made at the point of the boom for raising the boom sheaves in the event that excess dumping height is required. The performance of this machine shows a cost per ton of material delivered to the shaft that runs from 5 to 20 cents, as against a previous cost with hand labor of 25 to 60 cents. Its normal operating speed is three digger loads per minute, with a crew of two or at most three men.



**A mining machine that digs and loads in a drift into which ordinary apparatus could not go**

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



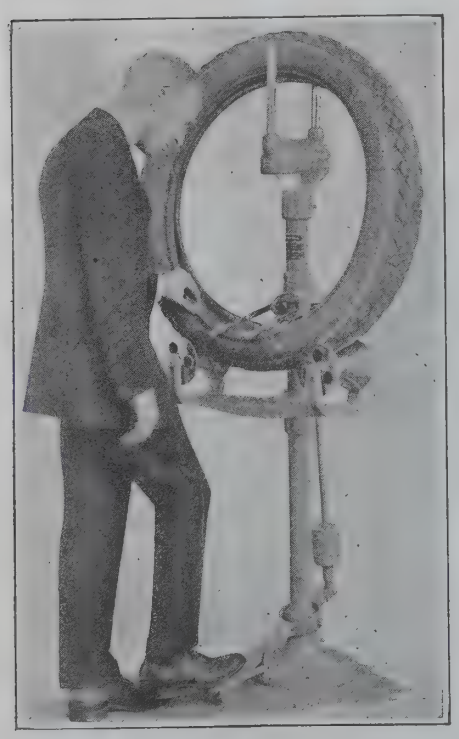
**A small flag swings around to indicate the temperature in this office desk thermometer**

## When a Small Flag Tells the Temperature

THE small flag mounted in the center of the office desk thermometer, shown in the accompanying illustration, swings around at the slightest breath and tells the temperature. The raised dial around which the flag travels is graduated like the face of a watch. So sensitive is the device that the slightest draught will send it on its way indicating the change. Not much thought has ever been given to the average temperature indicator, but in this recently patented design beauty has been added to accuracy, making an ideal combination.

## Finding the Small Breaks and Cuts in Tires

TIRE repair men do not depend upon their hands and eyes in the inspection of tire tubes with a new machine shown in the accompanying illustration. It opens and inspects the stiffest tire in ten minutes. The entire surface of any sized casing may be readily seen. It is then inspected thoroughly under a powerful concentrated light. All the small breaks and cuts which are generally at the bottom of much tire trouble may be found easily. It tells the unvarnished truth about your tire, so to speak.

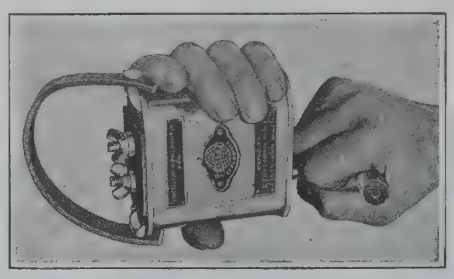


**The inspection of tires becomes a simple and positive job with this machine**

## A Pocket-Sized Electric Blasting Machine

WITH the blasting machine shown in the accompanying illustration, all that is necessary to fire the charge is to turn the key at the bottom of the electric blaster as far to the right as it will go. One turn is sufficient; and the key can be removed and carried in the pocket of the man in charge of the blasting, insuring absolute safety. The leading wires are connected to the binding posts of the blaster. It is light in weight and can be carried about easily.

It should be obvious that this little blaster is only intended for the firing of a few charges at a time. In fact, it has been developed by a powder company for the use of farmers and small contractors whose modest needs would make a large blaster a luxury, so to speak.



**One twist of the handle serves to operate the small electric blasting machine**

## Packing of Dyes, in Powder Form, for Dispatch to Foreign Countries

THE following regulations have been issued by the United States Post Office Department regarding the packing of dyes, in powder form, for shipment to foreign countries:

Dyes, in powder form, must not be accepted for transmission in the parcel post mails to those foreign countries admitting dyes in the parcel-post mails, except those dyes packed in a tin or metal container and such container inclosed in a substantial outside cover, open to inspection, of fiber board or similar material, double-faced corrugated cardboard, or strapped wooden boxes made of material at least a half inch thick.

The inside tin or metal container must be one closed with a screw-top cover having sufficient screw threads to require at least one and one-half complete turns before the cover will come off, the cover of which must be provided with a washer, so as to prevent possible sifting of the contents.

This provision for the employment of screw-top tin or metal containers does not prevent the use of compression (friction) tin top or metal containers, if soldered in at least four places, or the use of lead-sealed tin or metal containers, provided the containers are labeled in printing so as to show the nature of the contents, the quantity, and the name of the manufacturer or dealer, and, in addition, the containers are inclosed in substantial outside covers, open to inspection, of fiber board or similar material, double-faced corrugated cardboard, or strapped wooden boxes made of material at least a half inch thick.

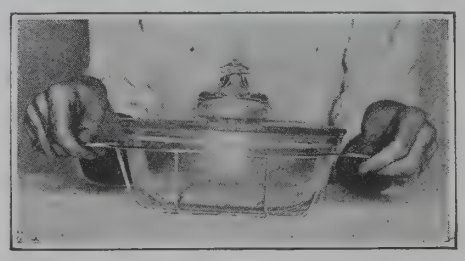
Acceptable packages of samples of dyes, in powder form, not exceeding 12 ounces in weight, and packed in accordance with the requirements of the Postal Union regulations, will likewise be received for transmission in the international parcel-post service, when postage is paid at the rate of 12 cents a pound or fraction thereof.

## Still Another Scheme for Harnessing the Wind

EUROPE is facing a serious shortage of fuel of all kinds. Coal, gasoline, wood, alcohol—all these common forms of fuel are lacking. In consequence the inventors of numerous countries have turned their attention to the power and heating problem, and many strange things have been suggested and tried out.

Among the many new ideas is the vertical wind mill shown in the accompanying illustration. This is a French invention, and it is reported to be quite satisfactory where the prevailing winds are more or less constant throughout the year. Among the advantages claimed for this form of vertical windmill or wind turbine are: Power no matter in which direction the wind is blowing; noiseless operation; the windmill does not have to turn about to face the wind, hence no loss of time; no danger of damage from strong winds or gales; five times the power derived from the usual forms of windmills; no mechanical upkeep or operating expense. The inventor is ready to undertake the building of such windmills in all capacities from ½ to 100 horse-power and over.

In order to take care of fluctuating winds, the windmill is employed in connection with an electric generator and storage battery. In this manner the mechanical power is converted into electricity and stored away until required. However, the inventor assures us that the windmill operates in practically any weather, and that only a few days are really lost throughout the year.



**The hot glass dish may be readily and safely handled in a wire frame**

## An Ounce of Wire Prevention

IT has not been long since glass was first introduced in which to make pies and other tempting dishes for the table. Our grandmothers, a few years ago, would hardly think such a thing possible— to bake in glass in place of tinned or enameled iron and crockery.

However, glass is coming into such general use that a manufacturer of wire novelties has conceived the idea of making wire frames into which these glass accessories of the kitchen may be placed while in the oven. The ounce of prevention is this. Hot glass dishes are hard to handle. Frequently when they are brought from a hot oven and placed upon a cold surface, they will crack. With the new wire frames both of these objections have been overcome.

As we have often pointed out in these columns, it is such inventions as this one which meet with a ready market. Indeed, there is a tendency to overlook the simple things in inventing; yet it is the simple things that usually take best.

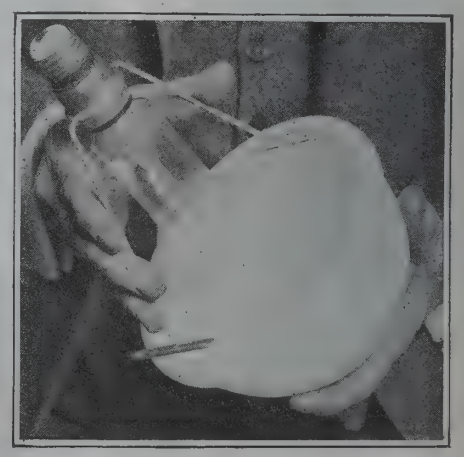
Copyright Keystone View Co.

**This French windmill may be built for any power from ½ to 100 horsepower, depending on the size**

## Could Anything be Simpler than This Lamp Bowl?

IT is certainly uncomfortable for the eyes to work before an unshaded incandescent lamp. Eye fatigue results, and if the practice is continued for long periods of time, the fatigue must necessarily extend to other parts of the body. At any rate those who make a special study of shop accidents tell us that fatigue causes men to become careless, and that most of the accidents occur between the hours of three and four.

Improper lighting is the greatest cause of eye fatigue, and despite the many advances made in improving working conditions in our shops and factories, one often finds no provisions for safe-guarding the eyesight of the workers. Reflectors cost money, to be sure, and their installation is often overlooked because of the expense and trouble involved. But the invention of a simple reflector and holder, recently placed on the market, removes the objections of trouble and expense. Indeed, so simple is the combination of the wire holder member and the translucent bowl that there is no excuse for failing to shield incandescent lamps in this manner. The shade or bowl may be snapped on or off for cleaning purposes, and the holder fits any incandescent lamp.



**Any incandescent lamp can be instantly fitted with the simple holder and bowl**

## Making the Barge Canal Pay

(*Continued from page 542*)

Lake Champlain Transportation Company has 24 barges, the Murray Transportation Company has 26 barges and the Transmarine Corporation has several fleets of steel carriers in operation on the waterway. There are, in addition to these, 500 boats of the old Erie Canal type owned or under charter to industries while many corporations have from 1 to 20 barges of special design in constant operation. These latter operators include the General Electric Company, American Radiator Company, Standard Oil Company and a number of cement companies.

Some of the corporations appear to have set out to use the canal to the limit of their needs. The channel had no sooner been opened last spring than the Standard Oil barges were on their way up the canal. This company brings oil to Albany in large tank steamers and pumps the fluid into storage tanks. From these tanks the oil is pumped into the canal tankers and shipped as far north as Burlington, Vermont, and as far west as Rochester. The company has stations at nearly every point of any size on the canal and, at several places where the Standard Oil has both rail and water connections, not one carload of oil was brought in by rail during the past navigation season. Some idea as to the extent to which the Standard Oil Company is using the State's waterway may be obtained when one is told that it has expended $110,000 in constructing a turning basin at Rochester. This clearly demonstrates that this big corporation, with its array of engineers, statisticians and economists, thinks that New York's Barge Canal is a going proposition and it certainly shows that the channel is a structural success.

The General Electric Company is also shipping a great deal of its finished products from its Schenectady plant to New York over the canal. This company reports that it can bring its water shipments from Schenectady to New York in the time it takes the railroads to get a car out of the company's yards and plans have been prepared which call for the construction of a private terminal at Schenectady to handle the General Electric shipments.

Despite this and other evidence that many shippers have found that shipping by canal is a paying proposition, there is still much ignorance among shippers relative to the waterway. A Buffalo manufacturer was recently complaining that he could not get his steel products to New York City. He said that the rail lines positively could not get the goods through. He was asked why he did not ship by canal and was surprised and startled to learn that there was such a route available. This is only one instance, but it shows the need of acquainting people with the availability of the Barge Canal.

The trouble is that almost a generation of men has grown up which thinks of transportation in terms of rail shipments only. This should be changed, and if it is done these shippers will think in terms of water routes as well as rail lines. If they once begin to think this way they will find that it is greatly to their advantage to utilize the canal system. What is required to bring this home to them is a "Ship by the Barge Canal" movement and this should not be limited to the State of New York but should cover the Great Lakes, New England and Middle Western States as well.

Shippers and industry demand relief from freight congestion. Because of the present lack of carriers, many have been disappointed in their search for cargo space in canal carriers. The Great Lakes shipper demands that his grain and other commodities be moved to the ocean at the cheapest possible rate and by the shortest route. He knows that recent increases in railroad freight rates, according to his schedule of costs, have placed him just 500 miles farther away from the seaboard than he was in 1918. In other words it now costs him as much to move his freight to New York as it would have cost him to have shipped it 500 miles beyond that port in 1918. He must have relief and the Barge Canal will afford him that if he will use it; for, now that capital knows that Federal operation of barge fleets will shortly be a thing of the past, it is constructing barge fleets and many responsible carrying corporations are being formed which will not only be in a position to approach the shipper and offer him cargo space but will also present him some workable plan whereby he will be guaranteed that his cargo will reach its destination within a stipulated time. In fact, one carrying corporation now moves its fleets on a set schedule and is extending its facilities by constructing its own terminals at Buffalo and Newark, New Jersey.

The reawakened interest in waterway matters does not rest here, for merchant marine interests, aware of the facilities the canal system affords, have become interested in the channel. This has been demonstrated by the movement recently launched by a prominent group of marine men who will shortly establish a waterway association that will give shippers and canal adherents, in general, a direct service. This organization plans to bring about coöperation between shippers, Great Lakes carriers, barge lines and vessels in the American Merchant Marine. It seeks to obtain low rates on goods which are to be exported and will, through coördination, enable the shipper in inland cities to bill his goods direct to Liverpool or other foreign ports via the Barge Canal.

In the steel trade, rail freight rates from Buffalo to New York amounted to $3.90 a ton in 1919 while the canal rate was $2.50 a ton or a differential in favor of the waterway of $1.40. Authorities believe that with proper organization steel can be shipped between Buffalo and New York for $2 a ton and, in fact, the Transmarine Corporation is offering to handle steel products to Bridgeport, Conn., at a rate of $2 a ton. With rail rates 40 per cent higher this year than they were in 1919 and using the suggested figure of $2 as a basis, the canal differential on steel would be more than 50 per cent. The same condition is true of iron ore and other commodities.

The original Erie Canal was constructed before the advent ot the railroads and for over fifty years it was the cheapest medium for transporting freight. With the development of the railways, however, the canal gradually lost its advantages so, in order to hold its position various enlargements were undertaken. These conditions lasted for a time but not for long, as the railroads were also improving their efficiency and lowering their rates. The explanation for this is easy to discover, as the cost of transportation is made up of two items, namely, a carrying and a terminal charge and, though the canal could move freight cheaper than the rail lines it had no public terminals, whereas the railroads had these aids. This placed our early canal at a great disadvantage and was the chief cause for its decline.

The construction of the Barge Canal, with its terminals, waterhouses and multitude of freight-handling machinery has wiped out the disadvantages of the old route and has, in addition, provided a means for handling freight at a cost which is less than that asked by the railroads. The rail lines have not been able to cut down their terminal charges to the same extent that they have their carrying charges, due largely to the fact that they have been more interested in transporting freight than in reducing the total cost of handling it.

The last Legislature appropriated funds to start the construction of State-owned grain elevators at Oswego and on the

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Pertaining to Apparel

GARMENT PROTECTOR.—K. HEITLER, 605 W. 141st St., New York, N. Y. The invention relates to the construction of a sanitary garment which encircles the limbs and abdomen of the wearer; the device is equally applicable to infants or grown persons of the female sex; it will permit a sufficient quantity of air to come in contact with the parts enveloped and permit the evaporation of perspiration although preventing the escape of any fluids.

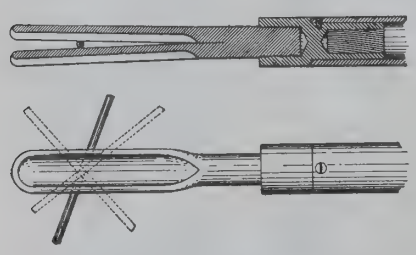
## Pertaining to Aviation

AIRPLANE.—P. T. WOLFE and W. H. BOVARD, 1241 West 38th Place, Los Angeles, Cal. An object of this invention is to provide an arrangement of rotary planes which serve to support the device in the air and to quickly elevate the same in a substantially vertical line or permit the descent thereof. A further object is to provide an airplane which can be operated to start and light without the necessity of running over the ground.

## Electrical Devices

ELECTRIC SWITCH.—H. F. IRRGANG, Box 72 St. Marlies, Idaho. The primary object of the invention is to provide a mounting for switch handles, which embody a movable bridge piece, which will completely safeguard the person manipulating the same against contacting with any of the charged parts of the switch in moving the bridge piece to break or make the circuit.

ELECTRODE HOLDER.—W. E. CLEMENTS, Oroville, Cal. The invention relates more particularly to electrode holders designed for electric welding, an object being to provide a construction of fork consisting of two spring



AN ELEVATION AND LONGITUDINAL SECTION OF THE DEVICE

members adapted to grip an electrode between them, these members being so shaped transversely as to give a three-point contact engagement with the electrode, thereby securely holding it but permitting of any desired angle in accordance with the operation to be performed.

WIND WHEEL ELECTRIC GENERATOR.—A. H. HEYROTH, Geraldine, Mont. The object of this invention is to simplify the construction and operation of generators of the character referred to so as to be more reliable and efficient in use, economical to manufacture, and so designed as to be used in combination with a rectifier, whereby continuous current can be obtained for the charging of storage batteries and other purposes.

## Of Interest to Farmers

FARM IMPLEMENT.—D. D. SOMMERS, Box 161, Champion Alberta, Canada. The principal object of this invention is to provide a bar which trails along beneath the surface of the ground for destroying weeds and heavy grass, either by pulling the weeds or grass up by the roots and leaving them on the top to dry, or by bending them flat with the top of the ground and covering them with earth to such a depth that they will decay.

SCARIFIER ATTACHMENT FOR ROAD GRADERS.—J. A. WILLIAMS, Box 152, Aurora, Mo. A purpose of the invention is the provision of a scarifier of simple and efficient construction having teeth of a form to permit additional metal being welded thereon when they become worn or broken, thereby eliminating any waste of the metal. The device is provided with means for attaching it to any standard form of road grader.

STEERING MEANS FOR TRACTORS AND OTHER VEHICLES.—R. TINKER, Box 292, Monmouth, Ill. This invention has particular reference to the steering of tractors where two frames are pivoted together on a vertical axes, the adjacent corners of the coupled frames being drawn together on either side as desired, which causes a lateral movement of the coupled frames one relative to the other for steering purposes.

## Of General Interest

SAMPLE CARD.—A. WEINBACH, 696 Howard Ave., Brooklyn, N. Y. The object of the invention is to provide sample cards for displaying samples of woven fabric and more particularly relates to cards on which the samples are carried by tabs detachably secured to the card, whereby a card formed of a single sheet of material is adapted to receive samples on both sides, the securing tongues being protected and concealed.

COLLAR BAR.—A. BROWN, c/o M. J. Graner Co., 334 5th Ave., New York, N. Y. The invention relates to collar bars for use at the front of a soft collar for retaining the adjacent ends in position, and more particularly relates to collar bars of the type presenting clamps at the ends between the members of which the opposed lateral edge portions of the collar are adapted to receive the clamp for making a neat fastening.

FISHLINE ATTACHMENT.—M. J. CROSBIE, 152 West St., New York, N. Y. The patentee provides a useful device easily applied to a fishline at any desired point for attacking the snell. The form of the device maintains the baited hook away from the line to afford an attractive lure and prevent tangling of the snell with or without the fish. The device can be conveniently applied and should prove especially useful for deep-sea fishing.

SECTIONAL SCAFFOLD.—J. J. MACKLEM, Goshen, Ind. This invention has reference more particularly to a sectional structure with bracing and locking adjuncts whereby the whole may be readily assembled and disassembled. The primary object is to provide a ladder scaffold which will be simple in construction, strong and efficient in use, and readily adapted to various conditions and locations.

COLOR INDICATING CHART.—J. F. KAUFMAN, 883 7th Ave., New York, N. Y. Among the principal objects of the invention are to quickly ascertain the colors which harmonize by contrast or by combination to vary the harmonizing colors correspondingly, to register the colors employed for identification, to shade and tint, key and coördinate colors correspondingly, and to mechanically ascertain from a given key any of the color harmonies desired.

ALLOY.—F. MILLIKEN, 55 John St., New York, N. Y. The object of the invention is to provide an alloy more especially designed for use in mine water valves and other devices subjected to weak acids. The alloy consists of the following metals in approximately the proportions specified: Copper 42-52 per cent, nickel 22-28 per cent, lead 22-30 per cent.

GYROSCOPIC TOP.—K. EDISON, c/o Harry E. Block, Spring Valley, N. Y. Among the aims of the invention is to construct a gyroscopic top which may be operated entirely independent of any cord in that it combines as an essential part of its mechanism an operating means for a gyroscopic wheel, and further, the invention combines a structure which will cause a continuance of the stabilizing feature even after a cessation of the rotation on the part of the wheel.

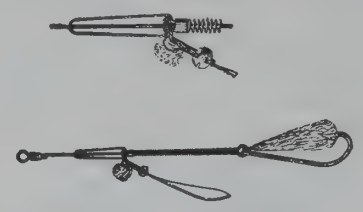
PASS BOOK.—T. P. MARTIN, JR., c/o Oklahoma Stock Yards National Bank, Oklahoma, Okla. This invention relates more particularly to a pass book construction which embodies a detachable inner pad in order to allow of renewal from time to time, the prime object being the provision of a cover permitting of ready use of the ordinary pass book pad in such manner as to show the depositor's name through a window in the cover.

BOTTLE CLOSURE.—C. E. BLANCHARD, 3811 Cottage Grove Ave., Chicago, Ill. An object of the invention is to provide an inexpensive bottle closure which may be secured to a bottle container liquid and which will substantially prevent the refilling of the bottle without detection. A further object is to provide a closure which hermetically seals the bottle, it being only necessary to cut off a portion of the closure to permit the pouring out of the contents of the bottle.

REVERSIBLE CHAIR.—F. S. PASCOE, Cristobal, Canal Zone, Panama. The invention relates particularly to a chair designed for use by a small child, an object being to provide a device which is reversible, so that when it is in one position it functions as a small rocking chair and when in the inverted position functions as an auxiliary seat for an ordinary dining chair to provide in effect, a high chair.

UMBRELLA.—R. ESTURO, 213 E. 80th St., New York, N. Y. This invention pertains more particularly to the handle structure of an umbrella. The primary object of the invention is to provide an umbrella in which the top is capable of rotary movement relative to the handle. A further object is to provide an umbrella in which the handle may be removed.

TROLLING SPOON.—J. T. MOORE, 407 East St., Eureka, Cal. The aim of the invention is to provide a trolling spoon device wherein the user may provide himself with one basic part and supplement such basic part



A PERSPECTIVE VIEW OF THE DEVICE

with different spoons, decoys and hooks, which are detachably secured to said part, thus saving a sportsman expense in outfitting himself for the catching of various fish. The substituting of one form of hook for another may be effected just as readily as the disengagement of the spoon.

RECEPTACLE CLOSURE.—D. BLOOM, 1526 McGee Ave., Berkeley, Cal. The aim of this invention is to provide a receptacle closure which will produce an absolutely air-tight closure. A further object is to so construct the device that it may be readily sealed by any one without the practice of any degree of skill, and although sealed in such a manner as to be air-tight, may be opened instantly. The closure may, after the opening of the receptacle, be used as a lid.

TABLE IMPLEMENT. — E. DE TEIXEIRA, Setauket, L. I., N. Y. Among the principal objects which the invention has in view are to provide a single implement for numerous uses, to meet the several demands for the preparation of food for personal consumption, to economize the transportation space, and to avoid loss of implements. The implement includes a table fork with cutting edge, spoon, corkscrew, nut cracker, can opener, cutting blade and a wedge-shaped end for cutting ice or similar service.

MILK CAN HANDLE.—P LAMBRAKOS, 206 E. 59th St., New York, N. Y. The invention relates to handle attachments, and more particularly to a handle device for clamping upon cylindrical bodies such as milk cans and the like to facilitate the handling and transportation of the milk cans. It is an object to provide a handle attachment having a rotatable element rigidly mounted on a frame, the whole of which may be quickly and conveniently attached to the can.

WINDOW SEAT.—L. VIEZZI, 435 W. 7th St., West New York, N. J. The object of the invention is to provide a seat for the accommodation of a person employed in washing, or doing other work outside a window; the device is arranged to permit of being conveniently and quickly attached to the window sill, and projecting sufficiently far out to enable the occupant to readily wash the window or do other work without danger of losing their balance and falling.

HAIR WAVER.—H. NATKIEL and I. FREEDMAN, 218 E. 122nd St., New York, N. Y. The invention relates to ladies' toilet articles. Among the objects is to provide a simple and easily manipulated device for curling or waiving hair. The device comprises two outer reversely bent bow-shaped bars rigidly connected at one end, and a third bar located between the first two mentioned, the third bar having a sinuous form upon which the hair is adapted to be wound, the ends of the bars being provided with a locking hook.

SPOOL.—B. N. KNOCHE, 219 Grand Ave., Baldwin, L. I., N. Y. The object of this invention is to provide an exceedingly light thread carrying spool. Another object is to provide a spool made from a single piece of material such as wood, wood pulp and the like, which is strong, and arranged to properly fit the spindle of the machine on which the spool is to be used.

TELESCOPE.—M. LICHTMAN, 172 E. 93rd St., New York, N. Y. This invention relates to telescopes, and more particularly to means for securing an eye piece and object glass to the telescope, and also a catch which is adapted to secure the barrels of the telescope in a plurality of positions. An object is to provide a telescope which is simple in construction so that it may be manufactured at a low cost.

## Hardware and Tools

PIPE WRENCH.—A. W. KIEFER, 1909 N. Keystone Ave., Chicago, Ill. Among the objects of the invention is to provide a pipe wrench which can be quickly adjusted under working conditions to firmly hold objects of varying size, to provide a device in which the gripping members will hold more firmly when a positive turning force is applied, and in which any worn or broken parts may be replaced at small cost.

SCRIBER.—L. VIEZZI, 435 W. 7th St., West New York, N. J. This invention has for its object to provide a scriber for use on squares and similar drafting tools such as are generally used by carpenters and other persons and arranged to enable the user to accurately set the scribe for conveniently drawing a desired line over the surface of the work. Another object is to permit the use of a pencil or a steel pin as the scribing tool.

WORK HOLDING CLAMP.—H. I. LAVERS, 30 Irving St., West Somerville, Mass. This invention relates generally to work holding clamps, and particularly to a clamp for holding portions of carpenter or cabinet work together until the glue used for uniting the same has become sufficiently set. It is the purpose of the invention to provide a clamping and forcing device in a single element so that the two functions are performed simultaneously.

GROOVE CUTTING TOOL.—J. A. LEWIS, 603 Kickapoo St., Hartford City, Ind. The object of this invention is to provide a tool adapted for rotary engagement within a piston ring groove of a piston and carrying a cutting blade whereby upon rotation of the tool upon the piston an oil groove will be cut, the particular advantage of the device being that it eliminates the necessity of placing the piston in a lathe to effect the cutting.

NUT LOCK.—J. A. YOUNG, Belair, Md. The invention relates to an arrangement for positively locking the nut on the bolt against turning, yet permitting minute adjustment and convenient application or removal of the nut. A further object is to provide a nut lock of that type in which the bolt is provided with

AN ELEVATION OF A BOLT AND NUT ENGAGED WITH LOCKING MEANS

a longitudinal groove, and the nut is equipped with an annular recess or chamber circumscribing the thread opening and adapted to accommodate a locking means in the form of a split ring adapted to simultaneously engage the bolt and nut to prevent the latter from turning on the former.

## Heating and Lighting

HUMIDIFYING RADIATOR UNIT.—F. E. GROSVOLD, address A. H. Shoemaker, Eau Claire Natl. Bank Bldg., Eau Claire, Wis. This invention refers more particularly to a radiating unit which has a receptacle for water bordering the edges of the heating space through which the heating medium is circulated. An object is to provide a unit having a humidifier associated therewith, which may be attached at any desired point of a complete radiator. The unit is suitable for any method of heating in which radiators are employed.

WATER SEAL VACUUM VALVE.—J. H.

(*Continued on page 556*)

## Making the Barge Canal Pay

(*Continued from page 553*)

Gowanus Bay Terminal in Brooklyn. The Oswego elevator will have a capacity of one million bushels of grain, while the Gowanus Bay structure will hold two million bushels. These elevators have been planned and their construction will be well under way in the near future.

The State of New York has done everything it could to make its waterway a success. The officials having to do with canal matters have exerted every effort to push the project to completion, and it is now strictly up to the people to cooperate and by coöperation obtain all the benefits to be derived from the full utilization of the canal system that has been provided. There are four definite lines of work which can be followed to make New York's waterway a great carrier. These are: First, to urge upon members of the Legislature favorable action on appropriations for the further development of canal terminals; second, to assist in the organization of competent operating companies and the construction of barges; third, to divert freight to the Barge Canal and urge similar action upon others; fourth, to seek coöperation between shippers and carriers and the coördination of fresh and salt water transportation facilities.

## Tuning and Testing

(*Continued from page 545*)

passes this test, it is running so smoothly that a new dollar or a pencil can be balanced on top of the engine and will stand without falling.

The defects which are found inside the engines are usually of the kind that can be detected only with the stethoscope. One such is what is known as "piston slap." This is a noise so small that no automobile engineer discovered it until other noises were eliminated by the construction of the smooth and silent engines that are being turned out today. It is notable that the discovery of this noise was made in American and not in European engines. The reason is that in many makes of motors, including several of the famous European cars, the pistons can slap persistently and no one can discover it because of other noises.

Of course, engines which fail to pass this test and are sent back for tuning up, must come again to the dynamometer rooms and eventually pass 100 per cent in every way.

Thus, in the finished product, the results of American quantity plus quality work come to a focus. The selection of metals, the scientific heat treatment which surpasses anything that can be accomplished by the judgment of the most skilled worker, the accurate machine work and the inspection which insures uniformity of product, have all contributed to an unequaled result. An engine is turned out that is without a peer and yet is turned out in large quantities and of so uniform and perfectly standardized construction that in case any one of its hundreds of parts needs replacement, the first piece that comes from the stock bin will fit and function perfectly.

A single example of the ultimate test of the results obtained, completes proof of American superiority. There is a single company operating a bus line in California which is now running 52 cars of a high grade American make and keeps in reserve only three cars to replace possible break-downs and to permit repairs, service, and overhauling. Each of these cars makes an average run of 340 miles a day. Some of them have been in service for years and at least eight of them have run up a total mileage of about 300,000 miles while one has passed 350,000 miles.

European production has offered nothing which can in any way compare with this record of American achievement either in quality or quantity manufacture.

## The Dawn of American Commercial Aviation

(*Continued from page 546*)

As to the useful load, this is represented by the following items:

| | Pounds |
|---|---|
| Passengers (11) | 1,980 |
| Mail | 500 |
| Crew (2) | 360 |
| Gasoline (230 U. S. gallons) | 1,437 |
| Oil (20 U. S. gallons) | 150 |
| Total useful load | 4,427 |

The total weight in flying order is therefore 12,883 pounds, or nearly six and a half tons.

This great weight is carried by biplane wings of an aggregate supporting area of 1,397 square feet. The upper wings have a spread of 103 feet 9 inches, while the lower wings are 74 feet 4 inches in span. The wing chord measures 8 feet and the interplane gap, that is, the perpendicular distance between the upper and the lower wings, 8 feet 10 inches. The overall length of the machine, from the stem to the trailing edge of the rudder, is 49 feet 3 inches, and the overall height 18 feet 9 inches.

The propelling apparatus consists of two naval type Liberty XII engines, which have a total consumption of 64.2 gallons of gasoline and 3 gallons of oil per hour for an output of 700 horsepower. The engines are mounted with their direct drive propeller between the wings on either side of the center line. An electric starter fitted in the cockpit enables the pilot to get under way without outside assistance. The full speed these flying boats develop is 85 miles per hour, while the landing speed is 50 miles per hour.

Perhaps the most striking feature of these air liners is their extremely sturdy construction. The generous size of wing spars and interplane struts as well as the obvious strength of the double-planked hull, built of Port Orford cedar, are likely to prove a revelation to the layman who still pictures aircraft as flimsy contraptions of sticks and wires.

The first of these Aeromarine liners last summer safely carried hundreds of passengers from New York to Atlantic City, Newport, R. I., Southampton, L. I., and other places on the Atlantic coast. These performances and the splendid war record of these flying boats are the best proof that the Key West to Havana airway will be operated with craft which fully deserve the confidence of the traveling public.

That the establishment of an airway between Key West and Havana saves the traveler both time and inconvenience will be obvious from the following: Travelers who arrive at Key West at 2 P. M. have to wait eight hours for the boat to Havana and the sea voyage consumes the whole night, the boat reaching the Cuban capital only the following morning. The Aeromarine liners now leave Key West half an hour after the arrival of the train and cover the odd hundred miles' distance to Havana in an hour and a quarter. The traveler is thus spared the inconvenience of a tedious sojourn in Key West and the even less pleasing prospects of seasickness before seeing Morro Castle, while the actual saving in time represents virtually a whole day.

What such a shortening of the trip between New York and Havana means to the man who has to take the trip owing to urgent business reasons or personal affairs is obvious. The experience of the London to Paris airway shows that people in a hurry invariably take the airway in order to escape the delays attendant upon inadequate rail and boat connections. But it may be expected that besides the man-in-a-hurry there are other travelers who will take to the air. The desire

(*Continued on page 557*)

A Modern Model

THIS business-like building was erected by the Modern Foundry Co. for present use as a pattern shop and storage building.

The top floor, with its middle bay extra-lighted and ventilated by the sawtooth is splendidly suited, not only to accurate pattern-making but to any sort of fine machine work.

The other floors are almost as well equipped, for the upper and lower ventilators, connected by double arms, insure balanced in-and-out air movement whenever they are opened.

Such liberal glass and ventilating areas are not necessary for pattern storage: but in case a manufacturing building is later needed at this site, this building will be an asset, not a liability.

And the fact that so far-sighted a concern chose Lupton Factory Sash and Pond Continuous Sash for the walls and roof of this model building is not without significance. We will send you literature on the technical features of these sash on request.

—Yes, the Modern Foundry Co. is using the Pond Truss design for their new foundry buildings, with highly gratifying results in both light and ventilation.

## RECENTLY PATENTED INVENTIONS

(*Continued from page 554*)

LINDSAY, 1117 Jefferson Ave., Brooklyn, N. Y. An object of this invention is to prevent the escape of steam and to render the thermostatic element quickly responsive to the level of water and to the contact of steam therewith so as to cause the valve to operate and maintain at all times a water seal at the valve outlet to prevent the escape of steam.

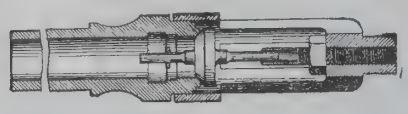
APPARATUS FOR RETURNING WATER TO BOILERS.—D. N. CROSTHWAIT, JR., Marshalltown, Iowa. The invention relates to means by which water may be fed or returned to a boiler from a level lower than the water line of the boiler. An object is to provide water return pumps or traps operated automatically by steam pressure applied to the body of water in the trap, and particularly by aid of an ejector located in the receiver and to which steam is directly admitted.

HOT AIR HEATER.—J. W. FIEBER, Shaw, Ore. The particular object of the invention is to provide devices for heating air for use in fruit evaporators, the heater is capable of utilizing a variety of heating means as well as one which will produce a very dry heated air and may be easily and quickly attended to. A further object is the provision of a heater by means of which the fruit may be dried with a proportionately reduced loss in weight and better color.

### Machines and Mechanical Devices

EMULSIFYING MACHINE.—J. F. SCHLAPPI, 1917 Grand View Blvd., Sioux City, Iowa. The invention has for its object to provide an emulsifying machine by means of which an emulsion between two or more substances not capable of chemical combination may be intimately mixed to form the emulsion. The emulsifier is simple in construction, easy to operate and inexpensive to manufacture.

VALVE STRUCTURE FOR OIL WELLS.—J. P. MCEVOY, Box 206, Sour Lake, Texas. An important object of the invention is to provide a structure with a view to increasing the efficiency and durability of the device. The



A CENTRAL VERTICAL LONGITUDINAL VIEW

valve structure herewith shown is of the reciprocatory type, and is employed in the well casing of an oil well. It may also be embodied in a standing valve structure, wherein the barrel or body portion of the device is stationary.

FLYWHEEL BALANCER.—M. MACHROL, 570 Prairie Ave., Kenosha, Wis. An object of the invention is to provide a device by means of which the surplus metal on one side of a flywheel may be readily located and removed. A further object is to provide a device having a scale which will indicate the amount of metal to be removed, and to provide a fly balancing device which consists of few parts, therefore easily constructed and not liable to get out of order. The device may be adjusted to flywheels of different sizes.

OIL RETAINER.—H. C. UTTECH and A. E. OHRMUNDT, Lebanon, Wis. This invention has for its object to provide a construction and arrangement of oil retainer in connection with a gear case or machine element of any character, which permits a free lubrication and yet which maintains a leak proof gasket around the shaft. The device dispenses with the necessity for the ordinary stuffing box and consequent frictional engagement with the shaft.

MACHINE FOR HANDLING ENSILAGE.—G. A. LONG, Mooresville, Ind. This invention relates to machines for handling ensilage and has for its object to provide a device especially adapted for use in silos for tamping the ensilage as it is placed in the silo, wherein the machine is operated by the feeding of the ensilage from the cutter; the ensilage is fed to the silo through a sectional pipe, the lower sections being removed as the silo fills.

SHANK BUTTON MACHINE.—B. VESELY and W. FAJMAN, address Bedrich Vesely, 1145 4th Ave., Astoria, L. I., N. Y. The invention has particular reference to means for forming shanks and drilling the eyes through the shanks of shank buttons such as are commonly made from clam shells, or other natural material or its equivalent. Among the objects is to provide a machine of a relatively simple, compact and reliable nature adapted for rapid manipulation.

FLEXIBLE COUPLING.—G. E. TOMLINSON, Winchester, Ky. This invention relates to a flexible coupling which may be employed in conjunction with any type of power-driven shaft where the driven shaft extends at a fixed or varying angle to the driving shaft, which coupling will require no attention whatever, such as oiling, wherein the wear will be reduced to a minimum, and which will be capable of absorbing shocks to a certain extent.

ADJUSTABLE CHASE AND LOCKUP FOR PRINTING, CUTTING AND CREASING PRESSES.—E. KARL, 20 W. Main St., Litchfield, Conn. An object of the invention is to provide a device which will securely clamp the plate and which is capable of a wide range of adjustment. With this mechanism the operation can be quickly performed and the device will securely clamp the plate or type set up, While the parts are adjustable, they are rigidly fixed when once clamped in position.

DEVICE FOR ARCHING AND FITTING SEMI ELLIPTIC SPRINGS.—J. I. ROBERTS, Box 635, Prescott, Arizona. The invention relates to devices for forming and shaping semi-elliptic springs. An object is to provide a device adapted more particularly for use in the blacksmith's shop. The device comprises a trestle, a presser frame with handle to be borne on by the operator, a fixed presser roll with a handle for turning it, and a companion presser roll with a swinging mounting on the frame.

APPARATUS FOR HARD TWISTING OF FINE AND THICK THREADS.—H. P. MITTET, Avlesund, Norway. The object of this invention is to provide an apparatus for hard-twisting of thread, to be placed on an ordinary twisting machine with pliers or a similar machine, by means of which the thread is given a sufficient twist, and from which the thread is passed directly to the twisting machine in a continuous process.

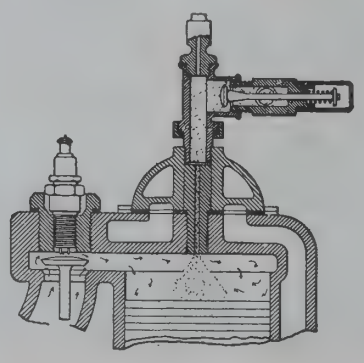
ROLLER CLEANER.—M. E. VAN BROCKLEN and R. HAIDEN, 4 Mohawk Place, Amsterdam, N. Y. This invention has for its object to provide a device adapted for use with spinning mules, for cleaning the rollers of the spinning jacks, wherein the arrangement is such that when the cleaner is placed upon the roller it will travel the full length of the roller, thoroughly cleaning the same, and requiring no supervision on the part of the spinner, and it may be used upon many machines.

### Musical Devices

MUSIC LEAF TURNER.—J. O. GEMSEY, Montevideo, Minn. The purpose of this invention is to provide a music leaf turner adapted to be applied to a music stand of the standard construction, which can be readily adjusted to fit the stand irrespective of its height, the turning mechanism being adapted to be actuated by the foot of the operator for successively turning the leaves as they are played.

### Prime Movers and Their Accessories

AUTOMATIC GRAPHITE LUBRICATING SYSTEM FOR INTERNAL COMBUSTION ENGINE CYLINDERS.—J. D. LOOG, 447 E. 173rd St., New York, N. Y. The invention relates to a system of lubrication in which finely divided flaked graphite is directly admitted into the cylinders without loss of compression. An



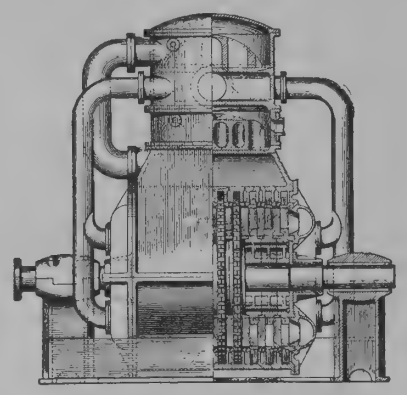
A SECTIONAL VIEW, SHOWING THE LUBRICATING SYSTEM

object is to operate the system automatically by the suction stroke of the engine in such manner that the graphite may freely pass directly into the cylinders, without the possibility of clogging the duct, and that the graphite on reaching the cylinders be distributed with the help of the inrushing gas vapor on the walls, where it forms a lubricating film.

POWER TRANSMISSION.—W. C. NUTT, Port Marion, Pa. An object of the invention is to provide mechanism for transmitting motion from a drive shaft to a crankshaft at right angles thereto. A further object is to provide a cam wheel and oscillating rame with rollers on the frame engaging the face of the cam wheel and compelling the movement of the frame due to the changing angular disposition of the cam wheel.

COMMUTATOR GRINDER.—F. E. FULLER, 1550 Williamette Blvd., Portland, Ore. This invention more particularly relates to a grinder or polisher for removing accumulations of dirt, and truing up the contacting surfaces of a commutator or timer for internal combustion engines. An object is to provide a simple grinder which is of such nature that it can be readily applied and easily removed.

MARINE STEAM TURBINE.—A. M. RODBERG, Box 1772, Tampa, Fla. This invention relates more particularly to a heavy duty reversible turbine for marine use, and among its various objects aims to utilize the expansive



A SIDE VIEW PARTLY IN SECTION

and impact force of steam to a maximum degree and at the same time provide for ready reversibility and similar speeds and power in both ahead and astern duty.

CARBURETING SCREEN.—F. W. LAPHAM, 5035 W. 33nd St., Cicero, Ill. The invention relates to a combined cylinder gasket and screen for use in connection with internal combustion engines. An object is to provide a screen arranged at or near the intake valve, and which is adapted to thoroughly atomize and vaporize the charge prior to its passage into the cylinder. A further object is to render the installation of the screen simple and easy.

COMBINED BY-PASS AND RELIEF VALVE.—E. B. WHELAN, 1025 S. 10th St., Omaha, Neb. This invention relates to that class of valves which are adapted to be used in steam engines of the piston-valve type, and individually to perform in such an engine, as occasion may require, the function of a by-pass valve and also the functions of a vacuum and compression relief valve.

### Railways and Their Accessories

RAIL JOINT.—D. MCEACHERN, Box 922, Nelson British Columbia, Canada. The invention relates to rail joints of that type wherein the ends of rails are not only connected, but are supported as well, so as to prevent excessive vibration of their contiguous extremities, the object is the provision of a simple means for maintaing the parts under an active tension at all times directed toward tightening the same and compensating for wear.

RAILWAY GATE CONTROL MECHANISM.—F. W. GRANT, 674 Marlborough St., Detroit, Mich. An object of the invention is to provide means without the use of a complicated construction, for the protection of street crossing railways by gates which are automatically closed by electrical energy on the approaching of a train from either direction, and automatically opened after the train has passed the crossing.

### Pertaining to Recreation

TOY MACHINE GUN.—H. ABRAMOWITZ, 176 Eldridge St., New York, N. Y. The general object of the invention is to simplify the construction and operation of toys of this character so as to be efficient in use, and inexpensive to manufacture, and so designed as not to readily get out of order. A more specific object is the provision of a machine gun which by operating a single crank, causes the projecting of a bullet and the explosion of a cap.

GAME BOARD.—EMMA N. LAMBERT, 511 Seminole St., Bethlehem, Pa. An object of the invention is to provide an arrangement of lines and spaces for use with game pieces for the playing of different games. A further object is to provide a game board which will be ornamental and attractive in appearance, and cheap to manufacture and entertaining in use.

### Pertaining to Vehicles

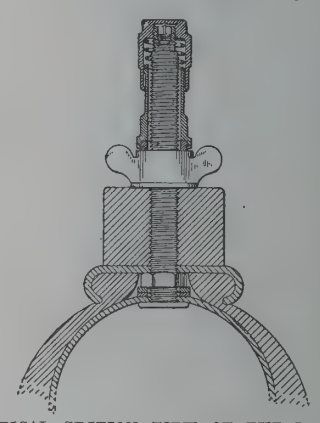
SPARK AND THROTTLE LEVER LOCK.—J. H. PRICE, 322 N. Ellis St., Cape Girardeau, Mo. The aim of this invention is to provide a locking device capable of ready adjustment to fit spark and throttle levers of slightly different spacing. A further object is the provision of an arrangement wherein means are incorporated to avoid danger of defeating the purposes of a lock by unwarranted opening of the quadrant and shifting movements of the spark and throttle levers beneath the lock plate.

PATCH HOLDER.—C. A. ERDLEY, Mifflinburg, Pa. The invention relates to a device for holding an inside blow-out patch within a tire while the tire is being placed upon a rim; the patch including flaps passing beneath the beads of the tire, clasps engageable with the flaps, and a member connecting the clasps, whereby they may be drawn snugly against the outer periphery of the tire to hold the flaps firmly and prevent shifting of the patch.

MOTORCYCLE SEAT.—M. E. WOOD, 255 1st St., South Amboy, N. J. One of the objects of the invention is to provide a tandem seat suspension which may be readily applied to a single seater motorcycle as an attachment. A still further object is to provide a seat embodying a self-contained construction in which a foot rest is provided, and employing an elliptical spring as the resilient means with means for adjusting the seat to accommodate the user.

WHEEL LOCK.—C. E. THOMPSON, 222 E. 89th St., New York, N. Y. Among the objects of the invention is to provide a wheel lock which is adapted to be secured around the tire and rim of a wheel to prevent turning movement. A further object is to provide a lock which dispenses with the necessity for a key and which cannot be operated except by a person having knowledge of the movements necessary to release the device.

DUST CAP FOR TIRE VALVE.—G. B. MULLEN, Bell Ave. and Broadway, Bay Side, L. I., N. Y. Among the objects of the invention is to provide in combination a closure for the valve stem and a dust cap in which is provided means to compensate for the varying thickness of fellies. A further object is to



A VERTICAL SECTION VIEW OF THE DEVICE AS APPLIED

provide a dust cap which reduces the time of labor required for the inflation of the tire to a minimum by obviating the necessity of separately removing the dust cap and the valve stem cap.

BLOW OUT PATCH.—W. VAN V. HAYES, 772 Park Ave., New York, N. Y. The invention relates generally to means for repairing pneumatic tires in such a way that the device may be used either as a blow out patch or inner lining or the like. The primary object is to employ a conventional type of patch in so far as concerns its body portion, but instead of using the ordinary flaps or aprons to so construct the flaps that the patch will not slip, creep or otherwise move from its strengthening relation relative to the tire.

### Designs

DESIGN FOR A JEWELRY HOLDER.—P. VIGGIANO, address Hugh M. Martin, Shinnston, W. Va.

DESIGN FOR A POURING SPOUT FOR CANS.—H. L. STRONGSON, 147 West Broadway, New York, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## The Dawn of American Commercial Aviation

(*Continued from page 555*)

to escape seasickness will probably be one of the causes, while the enchantment the aerial traveler experiences aloft will offer a further inducement to go *via* the air route. And European experience shows that the keenness of this latter class of travelers for air transport increases with each trip.

## In the Modern Saw-Mill

(*Continued from page 548*)

automatic unstackers facilitate handling.

Handling the refuse of a large lumber mill presents a considerable problem. It consists largely of dust, edgings, and trimmings and a large proportion of it is used for fuel. Shavings and dust are lifted by suction and blown directly to the fuel bins. Slabs from the slasher and stub ends from the trimmer are suitable for making broom handles, lath, and the like and after all usable material has been picked out, the waste goes to the "hog" which cuts the refuse up in small pieces for fuel.

Shingle machines are operated in connection with the mill. The lumber is cut into bolts for them and their action is entirely automatic. The din from a battery of these machines is deafening.

Not only does the waste from a lumber mill furnish sufficient fuel to operate all the machinery, but there are instances where the lumber company sells electric power to the local light and power concern, which in turn sells it to other consumers.

The transfer of lumber in and around the mill was for many years mainly done by means of hand trucks. Two electrical devices have replaced this antiquated system—the storage battery truck and the telpher or monorail. The latter consists of an overhead rail from which is suspended a car or cars, equipped with electric hoists, the operator riding in the car. The telpher is, of course, restricted in its movements and electric trucks are used for the miscellaneous hauling that has to be done.

Even in a plant where the fuel costs nothing it is important to have an economical steam installation, because the greater the steam demand the greater the investment in the boiler room and its maintenance. For this reason steam turbines have replaced reciprocating engines in many mills. In others, where the power requirements have outgrown the capacity of the plant, steam turbines have been installed which receive their steam supply from the exhaust of the old reciprocating engine. Such installations have been made to deliver one horsepower for every horse-power delivered by the original plant. In other words the capacity of the plant is doubled with no additional operating expense.

In some cases where the use of steam in a few operations is insisted on a mixed pressure turbine has been installed. This turbine consists of two elements, one of which operates on high pressure steam and the other on the low pressure exhaust steam from the auxiliary engines.

Certainly our big lumber mills cannot be accused of wasteful methods. They are manufacturing plants of the most efficient type, in which both material and human effort are conserved to a fine degree.

## Carbonic Acid Gas to Fertilize the Air

(*Continued from page 549*)

toward the plants, thus allowing extensive areas to be supplied with the fertilizing gas. On the opposite side of the greenhouse plant there was provided for checking purposes a plot of the same size submitted to no carbonic acid gas, the soil in the two plots being of the same quality. Samples were derived from the best portions of the checking field, but from the center of the field submitted to the action of carbonic acid gas, the increase in yield in the case of spinach being found to be 150 per cent, with potatoes 180 per cent, with lupines (a legume) 174 per cent, and with barley 100 per cent. The potatoes in the field submitted to the action of carbonic acid gas were found to ripen much more quickly than in the checking plot.

The testing plant in view of these surprisingly favorable results was eventually extended, three greenhouses of the same size as those existing being added, while the small open-ground plant was increased considerably and more extensive grounds—30,000 square meters—were provided with an underground central pipe and branch pipes encircling lengthy plots. Especially favorable results were obtained on this field with potatoes, a 300 per cent increase being recorded in connection with tests on a large scale.

All experiments so far made go to show that fertilizing the air by means of carbonic acid gas is a much more efficient process than even an increased fertilization of the ground with stable manure and cow dung. If, on the other hand, a plot fertilized from the air at the same time be submitted to soil fertilization, the latter, on account of the increased need for other elements (nitrogen, phosphorus, potassium, etc.) entailed by the increased absorption of carbonic acid, can be driven much farther than otherwise.

According to Dr. Riedel's calculations an iron works dealing in its blast-furnaces with about 4,000 tons of coke per day will daily produce as much as 35 million cubic meters of combustion gases, containing 20 per cent carbonic acid gas. This is such an enormous amount that even in the case of a partial utilization most extensive plots of ground can be supplied with the precious air fertilizer. Dr. Riedel therefore believes that carbonic acid works for supplying agriculture will before long be quite as common a feature as electricity and gas works, the large industrial centers at the same time becoming centers of increasing agricultural production.

Careful analysis has shown the increase in the percentage of carbonic acid in the air to remain far below the limit where the gas becomes liable to endanger the health of man.

## Mechanical Stevedore That Handles Bananas

(*Continued from page 549*)

suspended rigidly from above at intervals; monorail trolleys of 250 pounds capacity, having roller bearings to carry the bunch of bananas suspended from a special hook to which the bunch is hung by a loop device invented by Mr. Steckler for the purpose; and a power-driven chain provided with fingers at three-foot centers, in constant motion at the rate of 125 feet a minute, the path of motion being parallel to the monorail at such location that the fingers engage the suspended bunch of bananas, and thus push the trolley along on the monorail.

The accompanying photograph illustrates the device. One track (Loop L-1) is parallel with the ship. It connects with several switches, each swiftly operated by compressed air. Down one switch the bananas that are turning ripe are first shunted to the waiting cars or wagons. The green ones are diverted down another switch, following the entire line of box cars on the siding. From this main line switch, a dead-rail line branches out in front of each car. The dead rail is down grade to the car door, and the bunches of bananas are delivered there without human handling. There are bumpers to prevent the bruising of the fruit. After the trolley is unloaded, it is sent back to its point of origin by a separate return system, and is there reloaded for further use.

It will thus be seen that there are only a few trolley switchmen between shipside and the cars, where formerly at least 400 men were working. These switchmen

# Wire Rope at Panama

The value of wire rope in constructing the great ditch to connect east and west at Panama can hardly be overestimated. Not only were the powerful "muscles" of the giant shovels and material handling cranes wire rope, but a big factor in the disposition of immense quantities of soil and rock was also wire rope.

To unload the "spoils trains", steel plows were hauled from end to end by steel cable, pushing the waste material off one side. So great was the friction on the cable that smoke was usually seen at intervals along the top of the train where the steel cable was cutting its way into immense boulders picked up by the powerful shovels.

Before Yellow Strand Wire Rope, made by the Broderick & Bascom Rope Co., came to Panama, the best record for any one cable was 500 trains averaging 16 cars each. One Yellow Strand Wire Rope unloaded 1875 trains, of 17 to 19 cars.

Where there is extra heavy work to be done, Yellow Strand can be depended upon to do a giant's share.

There is a grade of Broderick & Bascom Wire Rope best suited to every purpose. They include the celebrated Yellow Strand of Panama Canal fame, which has one strand of yellow to distinguish it. Let your next cable be B. & B.

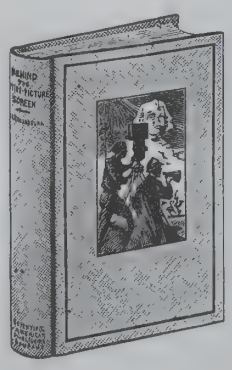
**BEHIND THE MOTION-PICTURE SCREEN**

*By* **AUSTIN C. LESCARBOURA**

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.



Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Size 6¼ x 9¼. $3.50; postage—15c in the East, 20c to Chicago, 30c to the coast.

*One of the Most Attractive Books Ever Issued.*

are also inspectors, who would have been employed anyway under the old system.

Under the old system, to unload a cargo of 35,000 bunches required seven to eight hours and the services of 400 laborers for distribution to cars, giving at least 2,800 man-hours at 50 cents, a total of $1,400, or about 4 cents a bunch. Under the new system the same cargo is unloaded in five hours or less; no laborers are required for distribution. The cost includes a special loop device (which cannot be salvaged) for each bunch, 35,000 at 1½ cents, $525; one chief and three assistant operator mechanics at a total cost of $27; power consumption for distributor system at $16; and upkeep, including oil, depreciation, $12; a grand total of $580, with a difference in favor of the new system of $820, or more than 2¼ cents a bunch.

By extending the system into the ship itself, there will be a still great saving in time and money. Mr. Steckler is working on a plan whereby the under side of each deck of the fruit ships will be equipped with monorails radiating to the hatch opening; from here the trolleys, loaded with bunches of bananas, will be lifted by a marine tower, similar to the present device, and so transferred direct, without further handling, to the wharf monorail system.

## The Sectional Unit Factory

(*Continued from page 550*)

by the simple expedient of adding more sections. Roof sections conforming to all the demands of the situation are to be had; and when the width is carried far enough to require one or more longitudinal rows of supporting columns, these are to be had, together with roof sections appropriately modified to meet the case. Our illustrations give an excellent idea of the manner in which these structures are put together, both with regard to the framework and the outer skin of steel and glass, and also leave the proper impression of extreme flexibility. On this point little more need be said than that lengths vary by multiples of two feet, the width of the wall sections; while widths vary by multiples of from four to ten feet, according to the style. It will be noted, particularly, that the standardized sectional factory is not limited to an absolute rectangle, but may have ells and wings as desired, as well as vertical skylights and other modifications of the roof outline. These buildings are in successful use in many industries, and appear to have a bright future. A more conclusive answer to the problems of the business that cannot afford to build, today, against the requirements of ten years hence, and can no better afford continually to be scrapping old buildings in favor of new ones, would hardly be imagined.

## A New Idea in Factory Heating

(*Continued from page 550*)

maintenance cost is equally low. It is portable, requires no special foundation, and can be moved and relocated by common labor, ready for operation within a few hours. The principle is simple: Cool air at the floor level (or from outside) is drawn into the unit by a powerful fan-wheel), heated in its upward passage around steam-heated coils or a heated firing chamber, and then discharged at low velocity through directing outlet hoods into the open area. The gentle current of air thus established does not create drafts or air-blasts that impair the health of the employees. Where steam is available, the heater simply takes the place of the usual radiator; where steam is not available, the direct-fired type is required. Even under the severest conditions this heater requires firing only every four or six hours, so that its operation does not call for much attention.

## Roller Bearings for Line Shafts

THE purpose of roller bearings is twofold: First, roller bearings reduce friction and thus reduce power losses; secondly, roller bearings by the same token resist wear. Hence it is with considerable interest that we hear of the success which has attended the use of special roller bearings for line shafts in various factories. Not only has a material saving in power been effected by the use of such bearings, but equipment of this kind has shown remarkable proof against wear and deterioration. For 29 years in some plants these bearings have been running easily and economically, saving power and lubricant.

## Gravity as An Aid to Production

A PRODUCTION system is no more efficient than its line of supply. Keeping high-priced skilled hands busy, expensive machines "fed," output steady and up to capacity, is the job confronting the production man in small shop and large factory alike.

The story of the gravity conveyor is an old one, all well and true; but there is a decided touch of the novel in the very latest gravity conveyor installations. The leading factories today are using gravity conveyors in carrying materials and products from operation to operation, floor to floor, from automatic lathes to assembly department and from there to the packing room and shipping platform. The human wheel-lug-and-carry system is obsolete. Its drudgery involves a class of labor that cannot be other than indifferent, unreliable, inefficient. And the wages remain exorbitant.

In comparison the gravity system means all the difference between the ox-drawn plow of antiquity and the tractor-drawn gangplow. The gravity system can be arranged so that the production methods are served in the proper sequence. Starting at one end of the establishment, the materials and assembled articles can be conveyed along until finally they reach the shipping platform. The gravity systems are now constructed with switching arrangements, so that at a moment's notice the path of the flow can be diverted to meet changed requirements. All in all, the gravity method is as efficient as it is simple, and as flexible as it is positive in operation.

## Results of the First Finnish Fair

THE first fair held in Finland was opened on June 27 and lasted 10 days. Its aim was to give a comprehensive picture of the industrial achievements of the country and of the progress and possible future development of its commerce and industries. There has been a better opportunity of organizing the industrial life of the country since Finland has been independent than there was before. Thus, for instance, it has been possible to establish chambers of commerce in the principal cities and in the centers of commercial activity. It was owing to their efforts that the first Finnish fair was organized and held.

All branches of Finnish trade and industry were represented. The foreign exhibit also was rather large and varied, although most of the foreign firms exhibited through their local representatives. The import restrictions, however, caused difficulties. Practically no bargains could be concluded and foreign exhibitors were disappointed.

As yet it is impossible to draw any conclusions in regard to the sales of Finnish products. Many factories are so busy that they cannot take orders except for future delivery. It was not expected that many foreign buyers would come here under existing conditions, and comparatively few came. The English, who are among Finland's best customers, did not take much interest in the fair, as they were already familiar with the products which they usually buy—timber and paper.

The fair has, however, brought many and has been of importance in that way. It has also shown the development of Finnish industry, and the general opinion is that it has been a success.

LEGAL NOTICES

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.

(14358) W. L. writes: I am enclosing you one of your notes and queries No. 14341 that I do not exactly understand. In this you give the weight of sea matter at the bottom of the deepest known depth as 77.12 and the compressibility as 20 per cent of 1/5 denser than at the surface and I have read in your notes and queries before where you gave the weight as about 67.5 and the compressibility as 1/20 or 5 per cent, and as they do not seem to agree I am writing you this letter. A. The compressibility of water varies considerably as the pressure and temperature increases. The pressure at the depth of six miles is about 1,000 atmospheres. The compressibility at that pressure is .0000358 per atmosphere, or .0358 at the bottom. This works out as about 1/20, or 5 per cent, as you state, about 67.5 lbs. per cubic foot at the bottom of the ocean. It was by an inadvertence that we used 20 per cent in place of 1/20 for which we express our regret. There is however some uncertainty in these figures and they should not be used as more than approximations. The figures as given in the Smithsonian Physical Tables for pressures up to 3,000 atmospheres at temperatures up to boiling may be taken as the best available, if one requires the most accurate result to be had.

## NEW BOOKS, ETC.

PHOTOGRAPHY AND ITS APPLICATIONS. By William Gamble, F.R.P.S. New York: Isaac Pitman and Sons. 12mo.; 132 pp.; illustrated.

A little different from the usual photographic handbook, this slim volume is rather a narrative of present-day photographical applications, prefaced by a brief historical sketch. Even though the reader may not be a practiser of the art, he will find this simple outline of operations attractive. It includes color processes, scientific and industrial uses, cinema work, and photography in warfare.

BUILDING SUBWAYS IN NEW YORK. By Fred Lavis. New York: Hill Publishing Company, 1915. 4to.; 73 pp.; illustrated.

This reprint of articles appearing in *Engineering News* during 1914 is a graphic account of an undertaking rivalling the Panama Canal in expenditure, with a total investment greater than many of our big railroads. The numerous problems presented and triumphantly solved make an absorbing story. A paper on the design of steel elevated railways, by Maurice E. Griest, rounds out an informative brochure.

ELECTRICITY. Its Production and Applications. By Reg. E. Neale, B.Sc. New York: Isaac Pitman and Sons. 12mo.; 136 pp.; illustrated.

Only a broad survey of the most salient features of the subject can be compressed into so small a compass, but as a review of the general nature of this force which has made ours the electrical age, of the methods by which it is produced and the many ways in which it is turned to account by man, this text performs a distinct service to the reader.

WHO'S WHO IN AMERICA. Vol. XI., 1920-1921. Edited by Albert Nelson Marquis. Chicago: A. N. Marquis and Company, 1920. 8vo.; 3,302 pp.

At one time, few men were deemed worthy of widespread interest until they had been dead for some years. Now we demand to know those who please us with a picture, a book, or an invention, or who occupy our administrative offices. The new issue of "Who's Who in America" has 23,443 biographies of such men; by turning to his own State or town in the geographical index, the reader will frequently be surprised to find some neighbor whose unostentatious work has won him national recognition. There is inspiration

Thirty Miles to a Gallon of Gas
WITH
# DOUBLE SEAL
PISTON RINGS

LEWIS INSTITUTE
CHICAGO

Nov. 11, 1920.

Double Seal Ring Company,
2335 S. Michigan Avenue,
Chicago.

Gentlemen:- Attention - Mr.K.D.Holland.

I've had my Ford car for three years. Two years ago I put in a set of Double Seal Rings. When I took them out 18 months later the cylinders were still giving excellent compression.

Then I had my cylinders rebored and put in a new set of Double Seal Rings. I did that because I was thoroughly satisfied that they would give me maximum compression.

I've driven my car 5,500 miles since then, and have gotten 28, 29, and even as high as 30 miles to the gallon right along, on country driving, with minimum carbon deposit. I haven't ground the valves or done anything to the car since that time.

The various tests I have conducted prove to me that there is no loss of compression when Double Seal Piston Rings are properly installed.

Yours very truly,
Oren G. Sherman
Assistant Professor,
Automotive Engineering.

Oren G.Sherman-
HS.

# RELATIVITY
## The Special and the General Theory
By Professor Albert Einstein, Ph.D. LL.D.
Translated by Professor Robert W. Lawson, M.Sc.

THE authorized English translation of Einstein's own book explaining his theories to the general public is now available. Dr. Einstein has scored a conspicuous success in this volume, steering a skillful course between the twin dangers of too much mathematics and too little explanation. Also, he makes clearer than has yet been made just wherein lies the dividing line between his special theory and his general theory, and just where the two join. In literary style as well as in clarity of exposition this book bids fair to take rank as a classic; and in any event, it is by far the most satisfactory treatment of the subject to be had at the presen date in English.

Price $2.50, by Mail $2.58

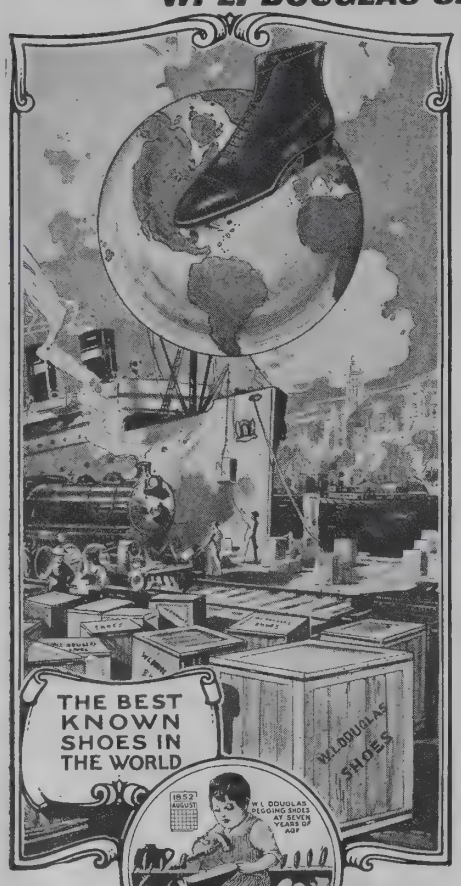
**W. L. Douglas**

THE SHOE THAT HOLDS ITS SHAPE

**$7.00 $8.00 $9.00 & $10.00 SHOES**

**FOR MEN AND WOMEN**

**YOU CAN SAVE MONEY BY WEARING W. L. DOUGLAS SHOES**



BOYS SHOES $4.50 $5.00 and $5.50

The best known shoes in the world. They are sold in 107 W. L. Douglas stores, direct from the factory to you at only one profit, which guarantees to you the best shoes that can be produced, at the lowest possible cost. W. L. Douglas name and the retail price are stamped on the bottom of all shoes before they leave the factory, which is your protection against unreasonable profits.

W. L. Douglas $9.00 and $10.00 shoes are absolutely the best shoe values for the money in this country. They are made of the best and finest leathers that money can buy. They combine quality, style, workmanship and wearing qualities equal to other makes selling at higher prices. They are the leaders in the fashion centers of America. The stamped price is W. L. Douglas personal guarantee that the shoes are always worth the price paid for them. The prices are the same everywhere; they cost no more in San Francisco than they do in New York.

W. L. Douglas shoes are made by the highest paid, skilled shoemakers, under the direction and supervision of experienced men, all working with an honest determination to make the best shoes for the price that money can buy.

W. L. Douglas shoes are for sale by over 9000 shoe dealers besides our own stores. If your local dealer cannot supply you, take no other make. Order direct from factory. Send for booklet telling how to order shoes by mail, postage free.

CAUTION.—Insist upon having W.L.Douglas shoes. The name and price is plainly stamped on the sole. Be careful to see that it has not been changed or mutilated.

W.L.Douglas

President
W.L.Douglas Shoe Co.,
163 Spark Street,
Brockton, Mass.

as well as information in this biographical dictionary of the living, and we are pleased to note its increasing use by the schools. The pronunciation of the more difficult names is indicated, and the birth and residence statistics show an increasing percentage of names from the western States.

KNOWLEDGE ENHANCED. By Luther Stockton Fish. 1903 Woodland Avenue, Cleveland, Ohio: C. Hauser, 1920. 8vo.; 297 pp.; illustrated.

The main thesis of this book is an attempt to explain sleep by locating the sleep effectuating mechanism of the body. This, the author avers, comprises the eyes, the optic nerves, the peduncles and the mammillaries, these last forming the electrodes of the system and sleep being dependent upon the breaking of their contact.

THE AMERICANS IN THE GREAT WAR. Milltown, N. J.: Michelin Tire Company, 1920. 8vo.; Vol. I., 130 pp. Vol. II., 146 pp. Vol. III., 112 pp. Illustrated; colored maps and plans.

These volumes, part of a series of illustrated guides to the battlefields, cover the activities of our men in the second battle of the Marne (Vol. I.), the battle of Saint Mihiel (Vol. II.), and the Meuse-Argonne (Vol. III.) The sub-title, "a panoramic history and guide," is fitly descriptive of the excellent work. Offensives and plans of attack and defense are briefly sketched, with admirable plates of the dispositions and movements. Plain directions are given the tourist for finding the points of interest. Both stay-at-home and voyager will be quick to appreciate the unique merits of the guide.

HOW TO FLY AND INSTRUCT ON AN 'AVRO.' By F. Dudley Hobbs, B.A. New York: Longmans, Green and Company, 1919. 8vo.; 75 pp.; illustrated.

The author demonstrates his familiarity with the best methods of teaching aviation. While the manual uses the "Avro" in illustration of theory and practice, the exposition holds good, of course, for any airplane. Embodying British experience in the war, it provides material aid to instructional efficiency in civil aviation.

ETHICS AND NATURAL LAW. By George Lansing Raymond, L.H.D. New York: G. P. Putnam's Sons, 1920. 8vo.; 345 pp.

Desires of body and of mind are not necessarily developed from one another; often we become aware of a conflict between them, and that awareness functions as "conscience." Such is the thesis from which Professor Raymond extracts a fundamental principle that largely reconciles existing ethical theories. Although very closely and academically phrased, and inclined to the platitudinous in its later chapters, the work is a reconstructive review of ethical theories, makes distinctions that have vitality, and will repay the necessary study and application.

THE YACHTSMAN'S ANNUAL GUIDE AND NAUTICAL CALENDAR. Boston (134 Milk Street): Clarence B. Hogg, 1920. 8vo.; 404 pp.; illustrated.

Delayed by fire in the bindery, this hardy annual so familiar to yachtsmen and motorboat owners yet celebrates triumphantly its forty-second anniversary. Besides the usual encyclopedic information regarding tides, ports, rigs, and handling, a new coast pilot section covers all points from the St. Croix River to the Chesapeake. A nautical dictionary, signal codes, tables, and club directories are among the items, and the numerous folding charts are as prominent a feature as ever.

PLEADING FOR JUSTICE. By W. C. Burns. New York: Justice Publishing Company, 1920. 8vo.; 316 pp.; illustrated.

A "purpose" novel, interwoven by a love story, the purpose being to interest the reader in the equalization of freight rates and government ownership of the railroads, after a plan designed by the hero.

THE THEORY AND PRACTICE OF AEROPLANE DESIGN. By S. T. G. Andrews, B.Sc., and S. F. Benson, B.Sc. New York: E. P. Dutton and Company, 1920. 8vo.; 454 pp.; illustrated.

Like all the volumes of the "Directly-Useful Technical Series," this text-book supplies such a combination of theory and practice as will best serve the thorough-minded man. The first twelve chapters elucidate general principles and properties, stresses and strains, design as applied to particular parts, stability and performance, whereupon follows a chapter in which these considerations are applied to the lay-out of a complete airplane. The authors have had the coöperation of leading British manufacturers, publishers, and the Advisory Committee, and have utilized to the greatest advantage a striking collection of plates and diagrams that often serve the purpose of clearing up obscure points instantaneously, and always lend interest and definition to the text.

EXPERIMENTAL WIRELESS STATIONS. By Philip E. Edelman, E.E. New York: The Norman W. Henley Publishing Company, 1920. 8vo.; 392 pp.; illustrated.

This work, used extensively in war training camps, has been rewritten to include all recent improvements; the engravings are entirely new. The text assumes some knowledge of mathematics and electricity, presents the best practice in plain language, and develops basic principles in detail. There is much material on vacuum tube circuits, radio-telephony, and the mitigation of interference. The ambitious amateur will find here all the information necessary to qualify him for serious work in the commercial field.

MOTOR BOATS AND BOAT MOTORS. Compiled and edited by Victor W. Pagé, M.S.A.E. New York: The Norman W. Henley Publishing Company, 1920. 8vo.; 524 pp.; 372 illustrations.

Owners and operators of motor boats will doubtless find this such a manual as they have been waiting for. Part I, dealing with the construction and design of hull and fittings, gives classification and types with all details from stem to stern, and offers material aid in the selecting of a boat for any particular service; it concludes with five popular designs—working drawings and full building instructions—by A. Clark Leitch. Part II scrutinizes the power plant and its auxiliaries, with the features of leading types, ignition and starting systems, operation, care and repair. A final chapter describes seaplanes and flying boats, floats, power plants, installation, and control. The boating enthusiast will be pleased with the completeness and practicality of the material.

PRACTICAL PHYSICS. By Millikan and Gale. Revised in collaboration with W. R. Pyle, B.S. New York: Ginn and Company, 1920. 8vo.; 462 pp.; illustrated.

For many years the basic material of this text-book has proved its worth, and in its new form it continues to emphasize the daily environment of the pupil as a source of mental stimulation, devoting much space to the internal-combustion engine, the airplane, and the lessons of the war insofar as they touch upon physics. In arrangement and treatment the work is much improved. The full-page portraits of physicists, and the cuts illustrating recent achievements, add value to an elementary text of high merit.

THE LOCOMOTIVE. Vol. XXXII. Hartford, Ct.: The Hartford Steam Boiler Inspection and Insurance Company. 8vo.; 253 pp.; illustrated.

Bound into book form, these 1918-1919 numbers of *The Locomotive* present the usual array of accident news and statistics, fuel economy hints, and steam boiler instruction. Those looking for the newer points and practice in safety and economy will find the articles and drawings of definite aid toward these desirable goals.

DYKE'S AUTOMOBILE AND GASOLINE ENGINE ENCYCLOPEDIA. By A. L. Dyke, E.E. St. Louis: A. L. Dyke, 1920. 8vo.; 940 pp.; 532 illustrations.

The latest edition of this standard work adds supplements dealing with special makes of car, trucks and tractors, motorcycles, and airplanes. It combines in one volume a reference work and instruction book, presenting in the simplest manner the fundamental principles underlying construction, operation, cars and repair. Everything picturable is shown in plates, charts, cuts, and folding inserts, so that little is left to the imagination, and frequently information required may be had by a glance at a drawing, and much time thus saved. The work has taken a deservedly prominent place as a practical instructor.

NEW GEOGRAPHY. Book One. By Alexis Everett Frye. New York: Ginn and Company, 1920. 4to.; 272 pp.; 650 pictures and maps.

Space will not allow mention of all the new features of this text. Topics are frequently introduced by means of a story; pictures, colored and uncolored, set the romance of industry before the child; the states are grouped according to industrial and climatic divisions—the War Department plan; industrial information is kept well to the front, and joined with history and civics to illuminate and emphasize geographical facts; the maps present a new color scheme, and none of the essentials of primary geography are slighted.

# FIRST *in* Public Utility Service

IN no other field of motor hauling do speed and dependability count as in public utility work. A five-minute delay in repairing a line might prove serious. Breakdowns need instant attention. The areas covered are often extensive. Emergency calls keep whole fleets on the go.

In the building and extending of telephone and telegraph, water, gas, railway, light and power lines, the hauling is heavy and the roads often bad.

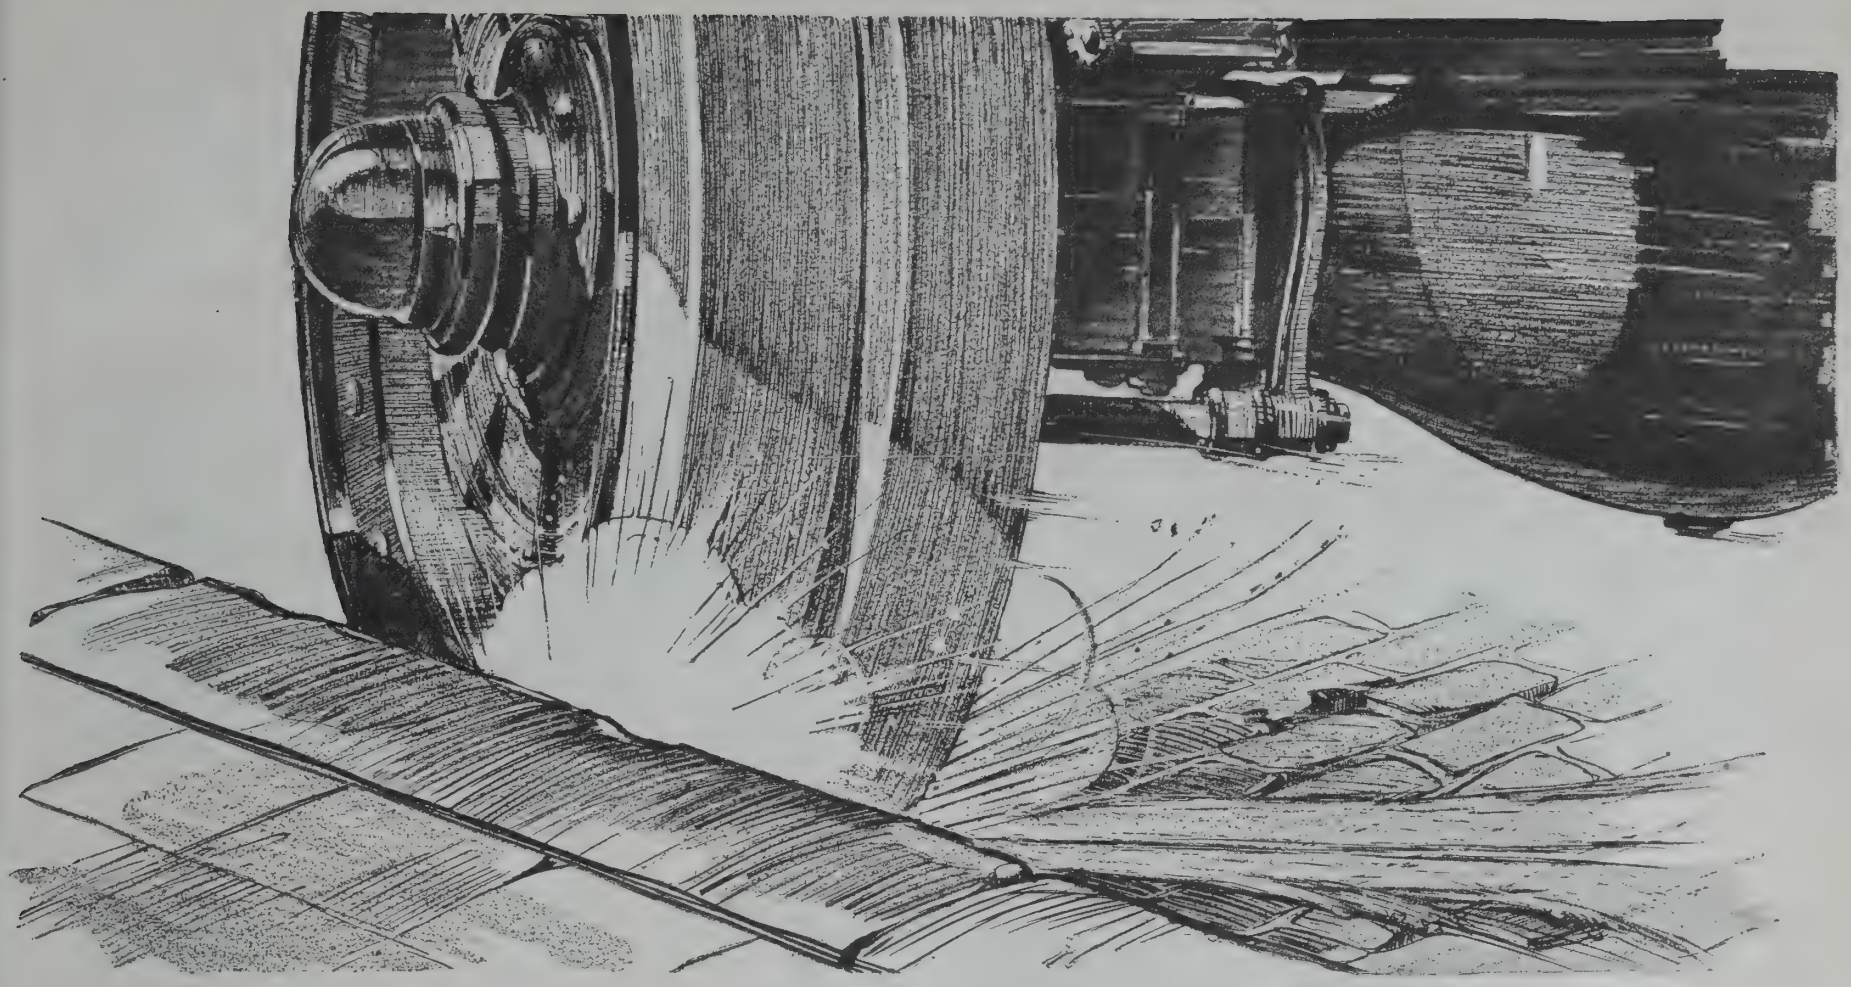
In this as in all other exacting fields, White Trucks are predominantly used. They have the stuff in them to stand up; as able to do a hard day's work after years of service as they were at the start. They are always ready and they *stay* ready. Year after year they continue to do the most work for the least money.

**A Summary of White Trucks in Public Utility Service**

46 Telephone and Telegraph companies own 635 White Trucks.
143 Electric Light and Power companies own 482 White Trucks.
64 Railway companies own 144 White Trucks.
77 Gas companies own 230 White Trucks.

THE WHITE COMPANY, *Cleveland*

# WHITE TRUCKS



# TIMKEN
## TAPERED ROLLER BEARINGS

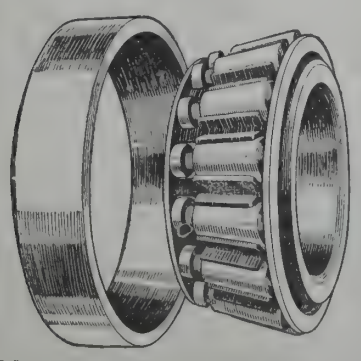
# Skid!

Zam against the curb!! Ten tons brought to a dead stop must give some shock to those rear wheel bearings!

But cheer up—the driver knows they're Timkens. He knows those "darned little tapered rollers" will stand up under most any old smash, from any old direction.

And what he likes about 'em is that if they ever do wear a bit, he can make 'em good as new in a jiffy.

## At Points of Hard Service



Timken Tapered Roller Bearings are used in the great majority of automotive vehicles at points of hard service:

Transmission — Pinion Shaft
Front Wheels — Differential
Rear Wheels — Steering Knuckle
Rear Axle Gears—Worm Gear, Internal Gear, Bevel, and Double Reduction.

This leadership is established on the tapered principle of design, quality of manufacture, performance on the road, and service to the automotive industry.

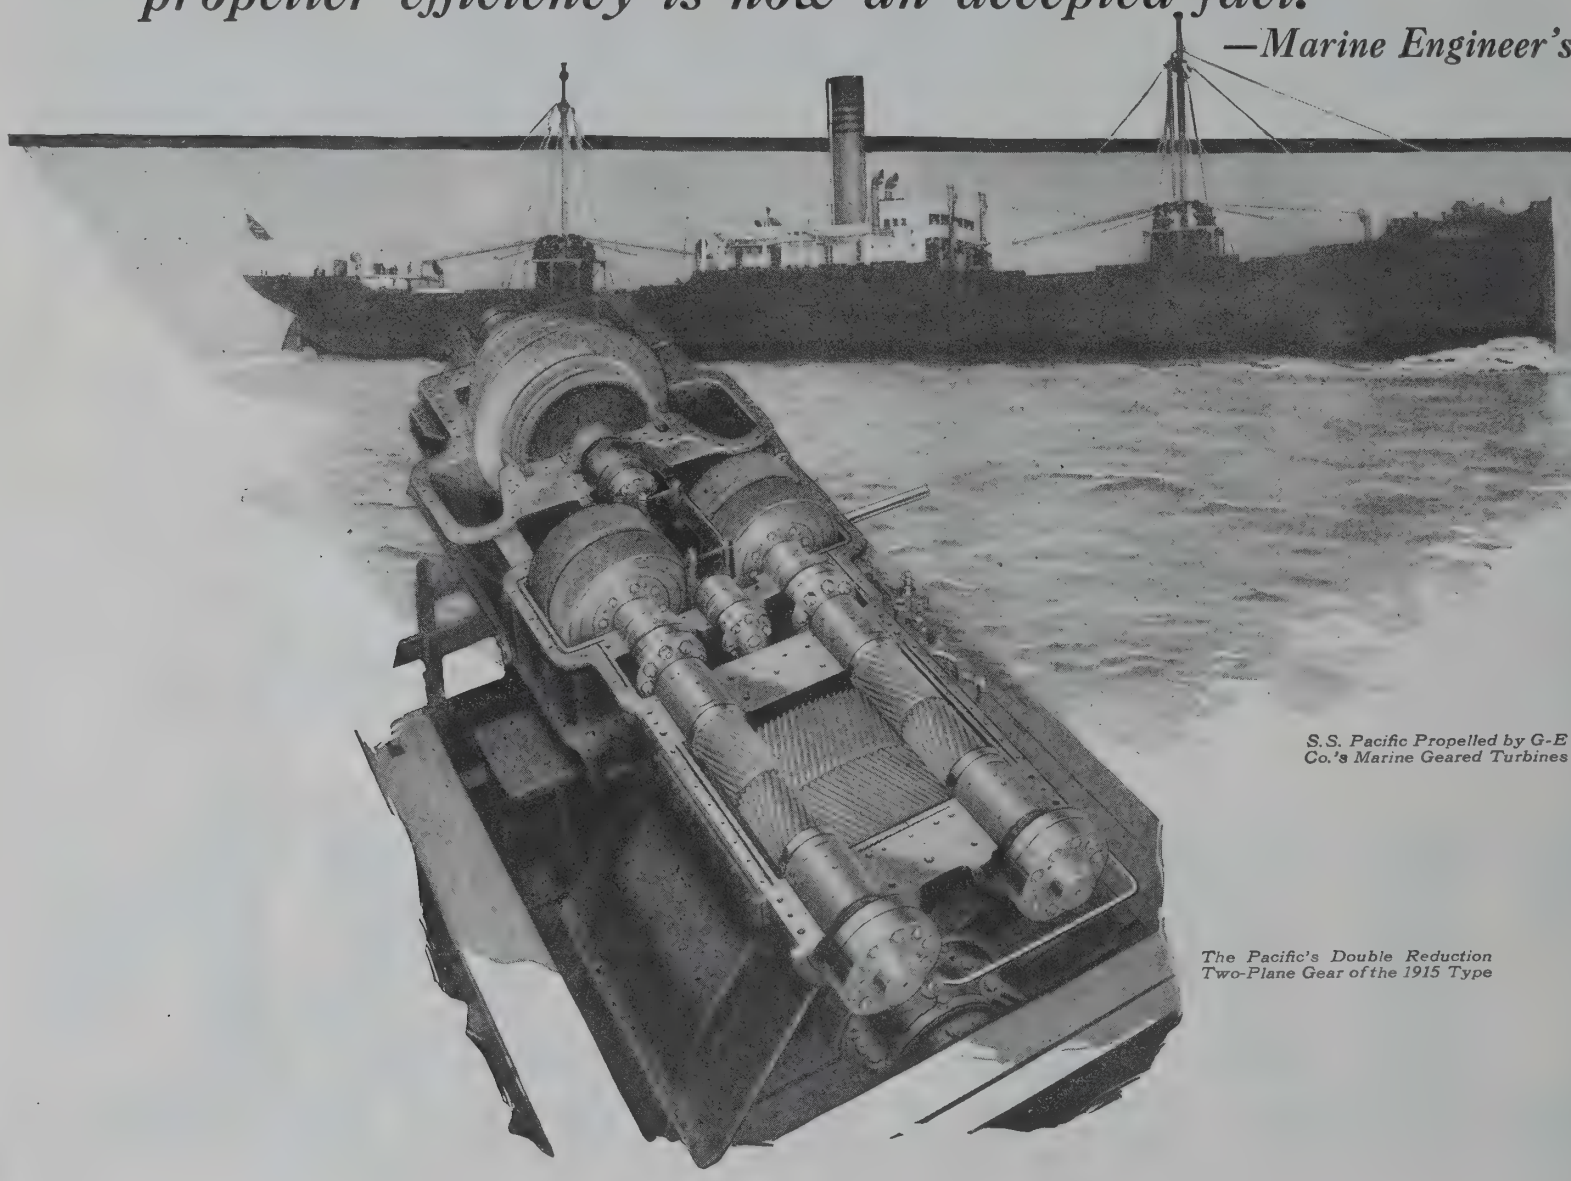
*"The advantage of gearing down the speed of shaft to suit propeller efficiency is now an accepted fact."*

*—Marine Engineer's Pocket Book.*



*S.S. Pacific Propelled by G-E Co.'s Marine Geared Turbines*

*The Pacific's Double Reduction Two-Plane Gear of the 1915 Type*

# This Marine Gear Has Stood the Test

THE first double reduction, two-plane type marine geared turbine ever put in commission on a merchant ship by any company in the world was on the S. S. Pacific. She went into general freight service in 1915 and has steamed through all sorts of seas under all kinds of cruising conditions ever since with practically no time laid up for repairs.

An inspecting engineer's report showed:

**G-E Record in the Merchant Marine**

| | |
|---|---|
| Units in service | 294 |
| Total H. P. capacity | 719,100 |
| Total ton mileage | 8,659,200 |
| Total miles traveled | 13,120,000 |

*After 210,000 miles, the Pacific's Low-Speed Gear was in excellent condition.* The Pacific's performance is an irrefutable argument in favor of the Curtis steam turbine and the two-plane, double reduction marine gear as built and introduced to the world by the General Electric Company.

The 1920 type gears have several refinements over the original 1915 type.

A general view of Seattle's new pier, second in the world in length and first in area

## Seattle's Record Pier

**By Ralph Howard**

THE Port of Seattle's new Smith's Cove Terminal Pier "B" is completed, and the fact that the port has made arrangements with two of the largest steamship companies on the Pacific Coast for the use of this terminal, shows the need of such a facility.

This pier is 367 feet wide and 2,560 feet long, only lacking 60 feet of being a half mile. It is the largest commercial pier in the world, even surpassing in square foot area the huge Chicago Municipal pier, which is 3,000 feet long.

This pier will have two transit sheds, 130 feet wide by 1,000 feet long at the street end, the outer section of the pier being uncovered, and given over for the handling of export freight. The north 500 feet of the east transit shed has been finished and as the construction crew were leaving the work, the "Horaisan Maru" began discharging 10,000 tons of cargo, consisting of nitrates, sugar, etc., into the transit shed for transshipment. Bids were requested for the construction of the north 500 feet of the west transit shed; these proposals were opened August 25, 1920, and the work contracted for at that time.

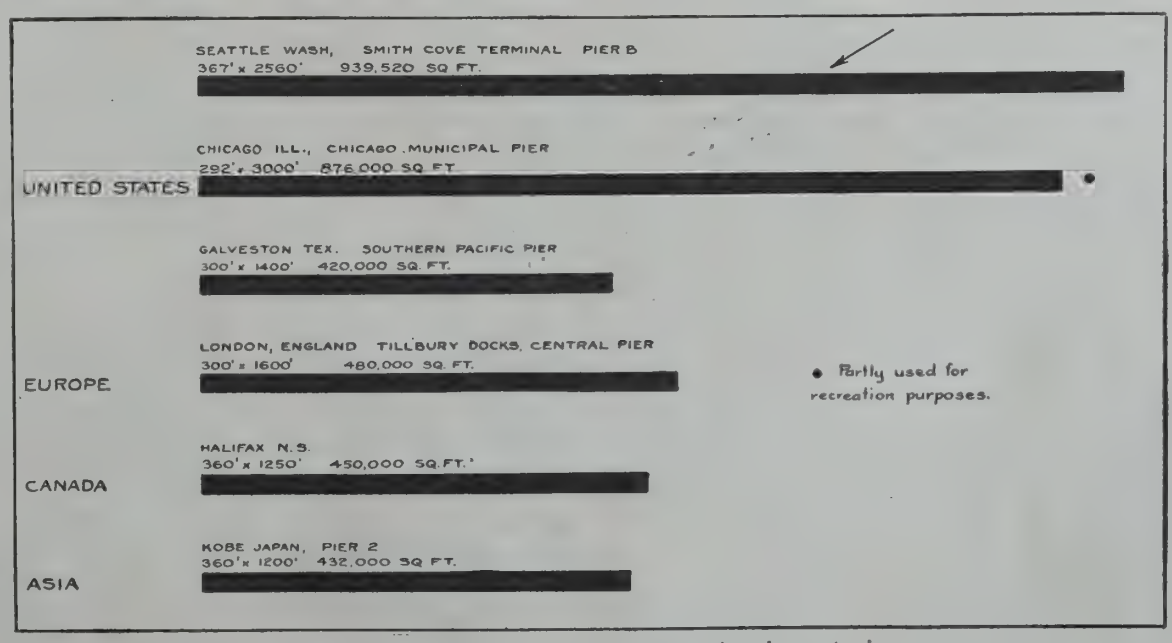
One of the outstanding features in connection with the equipment of this pier is the amount of railroad trackage, there being approximately 4½ miles of trackage consisting of two shipside tracks on outer sides of pier, together with four depressed tracks in the center, with numerous cross-overs in order to facilitate switching. It was decided to install this great amount of trackage since very satisfactory results have been obtained in the operation of the similar Smith's Cove Pier "A," which has 3½ miles of railroad trackage.

The port of Seattle has made satisfactory arrangements with the largest American steamship company on the Pacific Coast, and the largest Japanese steamship company entering Puget Sound for the use of Pier "B," the former being given preferential right for the use of the east side of the pier, while the latter has been given preferential right for the use of the west side of the pier. It is understood, of course, that when the ship berths and storage space are not used by either of these companies, the Port Commission will have the right to berth other ships and use storage space as required in order to place the terminal in maximum use.

Elaborate passenger accommodations and baggage inspection rooms are to be installed on the second floor at the street end of each shed for the accommodation of transpacific passenger traffic. A large commodious waiting room will be located on the water side of the second floor of each shed, this location being an ideal one from a fire hazard standpoint, besides giving the passengers easy access to the street. Just opposite and on the other side of the shed will be located the baggage inspection room, thus making it very convenient for the passengers.

Along the face of the pier, portable adjustable ramps will be provided, allowing passengers to leave the ship and enter the second floor in close proximity to the waiting and baggage rooms on an easy grade and without crossing any railroad tracks on the same level. The portable ramps will be made adjustable for any stage of the tide and will be electrically operated, making their operation simple and economical. Overhead bridges will be installed connecting the second floor of transit sheds with the overhead Garfield Street viaduct, enabling passengers to reach the street on the same grade, avoiding congestion of railroad and vehicular traffic on the lower floor from the time they leave the ship until they reach the street car line, taxicabs or waiting automobiles on West Garfield Street.

Since the oriental passenger boats also carry a large amount of freight, Smith's Cove Pier "B" will be most suitable for this class of business, for the import cargoes can be discharged and stored in the shed at the same time the passengers are leaving. To expedite the handling of this freight in the shed, a great variety of light handling equipment will be furnished. After the ship has discharged her passengers and her import cargo, she can then be warped along the pier to the large open wharf to take on her export cargo. Again, on the open wharf, a great variety of heavy mechanical handling equipment will be provided to expedite the loading of these vessels.



Graphic comparison of some of the world's largest piers

## Where the Lumber Goes

WOOD alcohol, as odious as it now appears in the public eye, has its proper uses. And the effort of the Forests Products Laboratory, Madison, Wis., to improve the quality of the liquid is legitimate—not, however, with the viewpoint of popularizing it as a beverage. Also, grain alcohol may in the future be extracted from waste wood accumulating around the sawmill or from scraps salvaged around newly-constructed houses.

From woodland to the bungalow in which you live, more than 60 per cent of the timber supply cut goes to waste, each of the transforming processes taking its toll of extravagance. How to utilize this large waste material is taxing the ingenuity of forest experts—the range of conservation involving anything from perfecting a better quality of wood alcohol to a baseball bat made from scrap lumber. Emphasizing the importance of recovering the huge timber waste, from the time it is felled in the forests until the last nail rivets the woodwork in the new house, the United States Forest Service has designed a unique model.

Situated on this diminutive scale of operations are representations descriptive of the successive stages through which timber passes—a growth of uncut trees, sawmill, planing mill, wood-working establishment, tanning factory, and a newly built home. Descriptive text is accessible to indicate the estimated percentage of loss credited to each of the varying processes of converting the trees into usable material.

At the fountain source of our timber resources—the growing woodlands—16 per cent is squandered in tops, limbs and stumps; 10 per cent is represented in edgings and trimmings; sawdust takes a toll of nearly 11 per cent; 10 per cent is wasted in slabs; bark represents nearly 11 per cent of waste; something over 5 per cent is lost in seasoning; careless manufacturing ioses 2½ per cent, while the planing mill renders irrecoverable still another small increment of something in excess of one per cent.—By *S. R. Winters.*

## Choosing a Secretary of the Navy

THE Navy has passed through more than one crisis in its history, and it is passing through a crisis today. The causes are many, and prominent among them are the policies, and even more, the mental attitude and outlook of the man who has filled the position of Secretary of the Navy for the past eight years. Selected for the position, apparently because of his out-and-out political sympathies, he found himself, on taking office, at the head of a vast and complicated institution of which technically he knew very little, if anything at all. With the spirit and traditions of the Navy, in their deeper and more spiritual significance, he seemed, from the very first, to be utterly out of touch—an estrangement, alas, which the passage of the years has seemed rather to accentuate than diminish.

And now we are to have a new Secretary, whose duty it will be to conserve the best of what the preceding administration has secured, and repair what many men within the Navy will tell you is the irreparable damage which has been wrought during the past eight years upon the traditions, the morale and the teamwork of the Navy as a whole. We believe that the following suggestions, as a basis of choice will commend themselves to those who have the highest interests of the Navy at heart.

In the first place, the Secretary should be selected as far as possible without any regard to his political color. We want no repetition of Danielsism. The Secretary's first thought and his last must be, not how this or that measure affects his political party, but how will his policies help to build up the Navy and make it a more effective instrument of defense?

Secondly, the new Secretary should have some knowledge of the Navy and its work, such, for instance, as was possessed by Mr. Daniels' able coadjutor, Mr. Franklin D. Roosevelt. Unless a man has had sufficient interest in naval affairs to possess himself of some knowledge of the history of the Navy, its present international standing and the functions of the various types of warships, he should be passed by. There are several men in political life who are qualified in this respect. They can be found in the naval committees both of the House and the Senate. Some, indeed, such as Senator Weeks, have passed through Annapolis and are thus admirably furnished to grapple with the questions of policy, personnel and materiel. It is a monstrous absurdity that a new Secretary should be so ill-informed as to have to learn the elements of the naval game at the very time when he is called upon to make decisions on the complicated questions which crowd in upon him from the very day that he enters upon his duties.

In handling the personnel of the Navy, the Secretary should play no favorites. He should be sympathetic alike with the officers and the men. He should have a full appreciation of the high code of ethics which is instilled into our young officers at Annapolis and which, we are happy to believe, maintains an ever-strengthening influence as they pass up to the higher grades. Nothing has been so disastrous in its effect upon the Navy as the belief which has grown up during the past eight years, that the present Secretary never grasped the meaning of that phrase: "As an officer and a gentleman." Whether the charge is justly laid at his door or not, we leave it to the impartial judge of his record to determine for himself. On the other hand, the enlisted men must feel that they have in the Secretary a staunch friend, who stands ready at all times to safeguard their interests, promote their material comfort, and hold open the door of opportunity. In this last regard the Secretary has done good work.

Lastly, since not even the State Department is brought into a more intimate touch with the outside world than is the Navy, the Secretary should be a man of wide international outlook and free from petty traditional dislikes and prejudices. He should understand that it is possible for an officer to give generous praise in recognition of the work of an ally, without incurring suspicion that he is lacking in true Americanism. True Americanism stands for Mr. Roosevelt's "square deal." It believes that a demand for the recognition of the rights of the people whom the Navy safeguards, is compatible both with the full recognition of the rights of others and a frank acknowledgment of their achievements in a common cause.

## Chess by Infants

CURRENT news relates the exploits of the eight-year-old Samuel Rzechewski, who has come out of Poland to conquer the world of chess. First-class players succumb to him; he gives simultaneous exhibitions against twenty average players with complete success; and Capablanca, at worst the world's second player, estimates that the United States may hold six men capable of giving him an even fight.

Chess has always been held up as the game of intellect par excellence; it has been taken for granted that only a rare combination of the highest mental abilities can qualify a man to play it with extreme skill. People who would realize that an infant prodigy in other lines is explainable on rational grounds are apt to be swept off the plane of common sense in discussing a Rzechewski or a Morphy.

The public at large and the mediocre player have little conception of the mental processes by which the masters of this game attain their results. Six years ago, in the Brooklyn-Washington telegraph match, one of the Brooklyn players undertook at about the twelfth move what appeared to be a highly hazardous sacrifice of a piece. A near-master in the gallery, a man whose journalistic activities are so heavy as to preclude his being among the very top-notchers of the game, spoke about as follows:

"That is the continuation employed by Blank against Dash at Hastings in 1896. In that game black defended so"—setting up the pieces on an idle board and running through the eighteen-year-old game from start to finish, never at a loss for the next move.

Turn from this scene to the rooms of the Manhattan or Brooklyn or Rice Chess Club, where we shall always find a gathering of the notable characters of metropolitan chess; and let us listen to the comments here made on a game in progress. Seldom do these comments take the form "If he goes here, black goes there; then white plays so and black so. . . ." Rather do we hear remarks like these: "But I tell you that *must* be strong—see the command it gives him of white's queen side"; or "Ach, he should have pushed the bishop pawn and built up his center"; or "What does he threaten? We have time for a developing move"; or "The isolated pawn ought to lose, in spite of the black king's being out of play."

The possible ramifications of any ordinary position in this game are well nigh infinite. Anderssen, one of the classical masters, in response to direct inquiry, said that when he was very fortunate he could see into the game as far as two moves. The good player does not analyze move by move, save in exceptional cases. His ability rests on two things. He remembers thousands of games that have been played by himself and others; thousands more of positions that are apt to be more or less closely approximated in actual play. He possesses the knack of putting out of his mind all other things when he is playing chess, and so doing he is able to master his memory and make it reveal to him in a flash the one game or the one position in all these thousands that throws light on the position before him. That is all there is to it.

Memory and attention do the trick. Memory is as likely to be found highly developed in a juvenile as in an adult. And once you get a juvenile with strong memory interested in chess, you have a strong player—for his experience gives him few things to conflict for attention with the board and men before him. All the amount of reasoning and analysis in the world are as nothing in the presence of the man who *knows* that in positions resembling this one the correct move is to occupy the open file with the rook or to post the knight on bishop's fourth, who can call to mind the complete course of a dozen games sufficiently similar to the present one to be a valid guide. That is the stuff of which chess prodigies, boy or man, are made.

## Our Engineers and the Public Service

AT the signing of the armistice the question arose as to how far it would be possible to make permanent the war organization of the engineers of the United States and render it effective in times of peace; and, as a result of a call to assemble and debate the matter in Washington, there was an enthusiastic response, which resulted in the formation of the Federated American Engineering Societies.

That the underlying purposes of this great and influential body include no narrow or selfish aims is shown by the following extract from the preamble: "As service to others is the expression of the highest motive to which men respond, and as duty to contribute to the public welfare demands the best efforts that man can put forth, now, therefore, the engineering and allied technical societies of the United States of America, through the foundation of the Federated American Engineering Societies, realize a long cherished ideal—a comprehensive organization dedicated to the service of the community, State and Nation."

At a meeting of the Federated American Engineering Societies held on August 18 at Washington there was launched the American Engineering Council of the Federated Societies, which henceforth will voice the aims of the united engineering forces in furthering a great national program of public service. The program proposes the following activities:

To devote itself to the conservation of our national resources, particularly in coal, oil, timber and water power. It proposes also to apply itself, immediately, to the great national problem of transportation, not only by rail, river and ocean, but by various subordinate but rapidly developing means of transportation.

It will take hold of the question of industrial relations between capital and labor, a matter regarding which the engineer, because of his comparatively impartial point of view, is believed to be especially equipped to make recommendations. We may remark here that by virtue of his very position, he stands midway between the two elements which too often in the past have regarded each other with suspicion and distrust. The engineer of necessity has to be in close touch with capital. On the other hand, to be successful, he must have a sympathetic understanding of contractors, foremen and so-called common labor.

Another movement to which the Engineering Council will devote itself is that of the creation of a national public works department by means of a reorganization of the Department of the Interior. Here is another question on which, by virtue of thorough experience, the engineers of the country are peculiarly qualified to plan and advise. Of prime importance, also, is the recommendation that the Engineering Council should guide legislation in the matter of licensing and registration of engineers. In view of the magnitude and costliness of engineering works, and particularly in view of the degree to which public convenience and safety depend upon good engineering, we consider this matter of licensing and registration to be of fundamental importance. Under the present system, too many half-trained and ill-adapted young men are passed on into this profession, with results which are injurious to the public and to the engineering profession alike.

Not the least important work of the council will be to coöperate with the Drafting Bureau of Commerce in its work of preparing for a national budget system and other important legislation. No one is better qualified to make estimates of cost than the engineer, or so quick to throw out proposals of national magnitude which are visionary and doomed to ultimate failure.

# That Parallel Postulate

## The Dividing Line Between Euclidean and Non-Euclidean Geometry, and What the Latter Means

### By The Einstein Prize Essay Editor

POINT, line and plane Euclid attempts to define. Modern objections to these efforts was made clear in our article of Sept. 18th. Against Euclid's specific definitions we urge the further specific fault that they are really assumptions bestowing certain properties upon points, lines and planes. These assumptions Euclid supplements in his axioms; and in the process of proving propositions he unconsciously supplements them still further. This is to be expected from one whose justification for laying down an axiom was the alleged obvious character of the statement made. If some things are too obvious to require demonstration, others may be admitted as too obvious to demand explicit statement at all.

Thus, if Euclid has two points A and B in a plane, on opposite sides of a line M, he will draw the line AB and without further formality speak of the point C *in which it intersects* M. That it does so intercept M, rather than in some way dodges it, is really an assumption as to the nature of lines and planes. Or again, Euclid will speak of a point D on the line AB, between or outside the points A and B, without making the formal assumption necessary to insure that the line is "full" of points so that such a point as D must exist. That such assumptions as these are necessary follows from our previous remarks. If we think of our geometry as dealing with x's, y's and z's, it is no longer in the least degree obvious that the simplest property applies to these elements. If we wish any property to prevail we must state it explicitly.

With the postulates embodied in his definitions, those stated in his axioms, and those which he reads into his structure by his methods of proof, Euclid has a categorical set—enough to serve as foundation for a geometry. We may then climb into Euclid's shoes and take the next step with him. We follow him while he proves a number of things about intersecting lines and about triangles. To be sure, when he proves that two triangles are identically constituted by moving one of them over on top of the other, we may protest on the ground that the admission of motion, especially of motion thus imposed from without, into a geometry of things is not beyond dispute. If Euclid has caught our modern viewpoint, he will rejoin that if we have any doubts as to the admissibility of motion he will lay down a postulate admitting it.

Having exhausted for the present the interest of intersecting lines, our guide now passes to a consideration of lines in the same plane that never meet. He defines such lines as parallel. If we object that he should show the existence of a derived concept like this before laying down a definition that calls for it to exist, he can show that two lines drawn perpendicular to the same line never meet. He will execute this proof by a special sort of superposition, which requires that the plane be folded over on itself, through the third dimension of surrounding space, rather than merely slid along upon itself.

We remain quiet while Euclid demonstrates that if two lines are cut by *any* transversal in such a way as to make corresponding angles at the two intersections equal, the lines are parallel. It is then in order to investigate the converse: if the lines are parallel to begin with, are the angles equal?

#### Axioms Made to Order

This sounds innocent enough; but in no way was Euclid able to devise a proof—or, for that matter, a disproof. So he took the only way out, and said that if the lines were parallel, obviously they extended in the same direction and made the angles equal. The thing was so obvious, he argued, that it was really an axiom and he didn't have to prove it; so he stated it as an axiom and proceeded. He didn't state it in precisely the form I have used; he apparently cast about for the form in which it would appear most obvious, and found a statement that suited him better than this one, and that comes to the same thing. But wisely enough, he did not transplant this axiom, once he had arrived at it, to the beginning of the book where the other axioms were grouped; he left it right where it was, following the proposition that if the angles were equal the lines were parallel.

This of course was so that it might appeal back to the demonstrated proposition for its claim to obviousness.

Euclid must have been dissatisfied with this cutting of the Gordian knot; his successors were acutely so. For twenty centuries the parallel axiom was regarded as the one blemish in an otherwise perfect work; every respectable mathematician had his shot at removing the defect by "proving" the objectionable axiom. The procedure was always the same: expunge the parallel axiom, in its place write another more or less "obvious" assumption, and from this derive the parallel statement more or less directly. Thus if we may assume that the sum of the angles of a triangle is always exactly 180 degrees, or that there can be drawn only one line through a given point parallel to a given line, we can prove Euclid's axiom. Sometimes the substitute assumption was openly made and stated, as in the two instances cited; as often it was admitted into the demonstration implicitly. But such "proofs" never satisfied anyone other than the man who made them; the search went merrily on for a valid "proof" that should not in substance assume the thing to be proved.

#### Locating the Discrepancy

Saccheri, an Italian Jesuit, would have struck bottom if he had had a little more imagination. He gave an exhaustive *reductio ad absurdum*, on the basis of the angle-sum theorem. This sum must be (a) greater than or (b) equal to or (c) less than 180 degrees. Saccheri showed that if one of these alternatives occurs in a single triangle, it must occur in every triangle. The first case gave little trouble; admitting the possibility of superposing in the special manner mentioned above, which he did implicitly, he showed that this "obtuse-angled hypothesis" contradicted itself. He pursued the "acute-angled hypothesis" for a long time before he satisfied himself that he had caught it, too, in an inconsistency. This left only the "right-angled hypothesis," proving the Euclidean angle-sum theory and through it the parallel postulate. But Saccheri was wrong: he had found no actual contradiction in the acute-angled hypothesis—for none exists therein.

The full facts were probably first known to Gauss, who had a finger in every mathematical pie that had to do with the transition to modern times. They were first published by Lobatchewsky, the Russian, who anticipated the Hungarian John Bolyai by a narrow margin. All three worked independently of Saccheri, whose manuscript turned up only in recent years.

Like Saccheri, Lobatchewsky investigated alternative possibilities. But he chose another point of attack: through a given point it must be possible to draw, in the same plane with a given line (a) no lines or (b) one line or (c) a plurality of lines, which shall not meet the given line. The word parallel is defined only in terms of the second of these hypotheses, so we avoid it here. These three cases correspond, respectively, to those of Saccheri.

The first case Lobatchewsky ruled out just as did Saccheri, but accepting consciously the proviso attached to its elimination; the third he could not rule out. He developed the consequences of this hypothesis as far as Euclid develops those of the second one, sketching in a full outline for a system of geometry and trigonometry based on a plurality of "non-cutters." This geometry constitutes a coherent whole, without a logical flaw.

This made it plain what was the matter with Euclid's parallel axiom. Nobody could prove it from his other assumptions *because it is not a consequence of these.* True or false, it is independent of them. Trinity Church is in New York, Faneuil Hall is in Boston, but Faneuil Hall is not in Boston *because* Trinity is in New York; and we could not prove that Faneuil Hall was in Boston if we knew nothing about America save that Trinity is in New York. The mathematicians of 2,000 years had been pursuing, on a gigantic scale, a delusion of *post hoc, ergo propter hoc.*

#### What the Postulate Really Does

Moreover, in the absence of an assumption covering the ground, we shall not know which of the alternatives (a), (b), (c) holds. But when one holds in a single case it holds permanently; so we cannot proceed on this indefinite basis; we must know which one is to hold. Without the parallel postulate or a substitute therefor that shall tell us the same thing or tell us something different, we have not got a categorical set of assumptions—we cannot build a geometry at all.

The reason why it took so long for this to percolate into the understanding of the mathematicians was that they were thinking, not in terms of the modern geometry and about undefined elements; but in terms of the old geometry and about strictly defined and circumscribed elements. If we understand what is meant by Euclidean line and plane, of course the parallel postulate, to use the old geometer's word, is true—of course, to adopt the modern viewpoint, if we agree to employ an element to which that assumption applies, the assumption is realized. The very fact of accepting the "straight" line and the "flat" plane of Euclid constitutes acceptance of his parallel postulate—the only thing that can separate his geometry from other geometries. But of course we can't prove it; the prior postulates which we would have to use in such an attempt apply where it does not apply.

To all this the classical Euclidean rejoins that we seem to have in mind elements of some sort to which, with one reservation, his postulates apply. He wants to know what these elements look like. We can, and must, produce them—else our talk about generality is mere drivel. But we must take care that the Euclidean geometer does not try to apply to our elements the notions of straightness and flatness which inhere in the parallel postulate. We cannot satisfy and defy that postulate at the same time. If we do not insist on this point, we shall find that we are reading non-Euclidean properties into Euclidean geometry, and interpreting the elements of the latter as straight lines that are not straight, flat planes that are not flat. It is not the mission of non-Euclidean geometry thus to deny the possibility of Euclidean geometry; it merely demands a place of equal honor.

#### The Geometry of Surfaces

Let us ask the Euclidean geometer whether he can recognize his plane after we have crumpled it up like a piece of paper en route to the waste basket. He will hesitate only long enough to recall that in the special case of superposition he has reserved for himself the privilege of deforming his own plane, and to realize that he can always iron his plane out smooth again after we are through with it. This emphasizes the true nature of the two-dimensionality which is the fundamental characteristic of the plane (and of other things, as we shall directly see). The plane is two-dimensional in points *not* because two sets of mutually perpendicular Euclidean straight lines can be drawn in it defining directions of north-south and east-west, but because a point in it can be located by means of two measures. The same statement may be made of anything whatever to which the term "surface" is applicable; anything, however crumpled or irregular it be, that possesses length and breadth without thickness. The surface of a sphere, of a cylinder, of an ellipsoid, of a cone, of a doughnut (mathematically known as a torus), of a gear wheel, of a French horn, all these possess two-dimensionality in points; on all of them we can draw lines and curves and derive a geometry of these figures. If we get away from the notion that geometry of two dimensions must deal with planes, and adopt in place of this idea the broader restriction that it shall deal with surfaces, we shall have the generali-

(*Continued on page 579*)

*OUR intuitions, if we give them free rein, will accept Euclidean geometry as the absolute truth about the space in which we are immersed. But in our article of September 18th we saw that no geometry can be the absolute truth about anything. The most that can happen is that a given set of objects, real or conceptual, constitute a realization of the geometry. To understand clearly the limitations of Euclid's geometry, we must go back and put ourselves in Euclid's shoes —as far as this can be reconstructed, in Euclid's very frame of mind. And let it be understood that the Euclidean geometry of this discussion is the scientific structure of a Euclid, a Klein or a Hilbert—not the pedagogic one of a Wentworth and a Smith with which most of us are better acquainted.*—THE EDITOR.

# Illiterate Adults

## Our Growing Population That Reads and Writes in Other Languages or None at All

By Winthrop Talbot, M.D.

**Men unable to read or write in any language, receiving instruction at the expense of their employer**

IN this country each year a million boys come to be 18 years of age. One hundred thousand of them have never had any schooling at all. They are technically illiterate. Illiteracy may be defined as inability to read or write in any language, and this definition applies throughout the following article. It should be understood that statistics of adult illiteracy deal only with persons who are over 14 years of age and who are beyond the obligatory school age. In addition to the one hundred thousand technical illiterates, two hundred thousand more have not had more than two years of schooling or three hundred and twenty days and about half of them have had but one year or 160 days of attendance at school. These two hundred thousand boys are practically illiterate for they have left school so young that as men they have retained but little of their schooling. More than half of the million barely reach the sixth grade, and a scant hundred thousand ever get as far as high school.

Nineteen States do not require the full school year of 200 days. Eight States require less than one hundred days. The average school year is only 163 days. One State has failed until now to make any schooling obligatory.

Less than ten per cent of all males get any kind of vocational or trade training at school. Fifty thousand of our million 18-year-olds do not speak any English at all. Among the million youths physical defects are general, due in large measure to ignorance. Two hundred thousand of the million would be rejected as unfit to serve the country because of extreme physical, moral, or mental defects. We certainly cannot congratulate ourselves upon any alarmingly high standards or effective results in our schooling of youth in America thus far.

How is it with our foreign adults and negroes and native whites? In 1910 we had five and a half million (5,516,163) persons who could not read a word in any language. Of these a million and a half were foreign-born. Now in 1920 we have nearly two million and a half illiterate aliens who cannot read a word even in their own languages. For example, from 1910 to 1914 inclusive, we admitted 971,366 immigrants from southern Italy and of these 415,806 or 49 per cent could not sign their names or read even the simplest Italian words. These are technical illiterates, but almost all Armenians, Turks, Russians, Bulgarians, Ukrainians, Croats, and Yiddish speaking peoples come practically illiterate to America, even though they may be able to read and write in their own languages, because their script and printed letter forms are quite different from ours.

The near-illiterate or those who can barely write their names and who decipher words only with difficulty are nearly four times as numerous as the technically illiterate. If now we take into consideration our negro population and unschooled native whites, it is easily grasped that in our total population we are all seriously handicapped by the intellectual dependency and mental pauperism of one quarter of our American population. This vast number, more than twenty-five millions, is cut off from ability to share properly in our national life. They form the drag on labor. They contribute mainly to our defective and criminal classes. They are the "examples" of our radical agitators.

Seventy per cent of industrial accidents occur to persons who require the services of an interpreter in presenting their claims. In most cases those who are injured are unable to read even a danger sign. In New York State alone from 1915 to 1918 accidents in industry have averaged 274,763 annually. In other words the number of industrial accidents averaged more annually than the total casualties of the American Expeditionary Force. The figures are as follows: 1915, 225,391; 1916, 273,385; 1917, 313,406; 1918, 286,871. At present industrial accidents are reported at the rate of approximately a thousand a day every working day in the year in this one State. This represents an initial expenditure of $13,000,000 a year for compensation. If we add to this the cost of medical benefits, administration of the compensation law, wages and cost of turnover, the total is about $25,000,000 yearly or $80,000 a day for accidents only to those who do not understand the American language.

This is the accident cost of the illiterate in this one State alone. What is true of the State of New York is also true of the whole manufacturing belt of the North, as well as of mining States such as West Virginia, Colorado, and Idaho. Thus a quarter of a million dollars a day is a moderate estimate of the cost of the illiterate to industry in the United States for accidents only, due in large measure to inability to read a danger sign or to understand ordinary safety instructions, and because of lack of a common language.

It is generally known that steel and coal strikes with their attendant loss of production and wage, as well as strikes occurring in other industries employing large numbers of foreigners are fomented readily because of inevitable misunderstandings due to diversity of speech. In many industrial plants twenty or more races of men are employed speaking as many languages, unable to read common work notices, and thus incapable of ready assimilation or industrial teamwork.

During the fifteen years from 1900 to 1914 inclusive, the total number of immigrants to the United States beyond school age, that is, over 14 years of age, was nearly twelve million (11,726,606). Of this number more than three million (3,116,182) could not decipher a word in their native tongue and practically all

(*Continued on page 580*)

*THE tremendously increased opportunities for acquiring the rudiments of an education today, as compared with a century ago, more or less, are apt to blind us to the necessity of some steps that shall insure the utilization of these advantages by the maximum proportion of the population. We take it for granted that everybody can and therefore that everybody does learn to read and write. The experience of those in charge of the great draft-act administration was perhaps the first suggestion that there exists in our midst a body of men and women aggregating ten per cent of the whole who can not read or write in any language. Dr. Talbot, as the author of several Federal bulletins on the situation and one who has dealt with it in public schools and industrial plants, is well qualified to tell us the extent and seriousnesss of this problem.*—THE EDITOR.

*Left:* A truck that was used to do all the hauling for a mountain orchard, and that came through with flying colors. *Right:* Using a motor truck to deliver manure to the point of final deposit

**Two of the many tasks which a motor truck can perform cheaply and efficiently for the orchardist**

## Motor Trucks in Orchards

**By Arthur L. Dahl**

NATURE is slow in growing to maturity fresh fruits, but once they have reached that state of perfection they deteriorate more or less rapidly, and the greatest task of the orchardist is in marketing his fruit crop in the quickest possible time and with the least amount of spoilage.

The time of harvest for most fresh fruits is limited to a month or so, and the most bountiful crop will not put dollars in the bank unless the fruit is delivered to a buyer in good condition; and in aiding the fruit grower to harvest all of his crop and make delivery to the purchaser in the best possible condition, the motor truck is playing an important part in all sections of the country.

In modern times a large proportion of the fruit grown in many sections of our country is sold to canneries, and these canneries have very strict and rigid standards for fruit, and the prices paid for deliveries made by orchardists are based upon those standards. In too many cases fruit growers living some miles from the cannery have left home with a load of fresh fruit in good condition, but on account of the heat of the sun and the length of time required to reach the delivery point with a team, the freshness of the fruit was largely lost and the owner was severely penalized for this condition. Now this orchardist may have devoted as careful and intelligent attention to the production of that fruit crop as any of his neighbors, but because his transportation facilities were slow and inadequate, he suffered the loss of a large share of the profit he should have had.

The first point of superiority of trucks for orchard use is speed in making deliveries. A truck, even though loaded to capacity, can make better time than horse-drawn vehicles, and in the movement of a large tonnage of perishable fruit, this might mean the handling of double the amount of fruit in the same time, compared to horses. The saving in time in making deliveries is in proportion to the distance hauled, for the longer the haul the more time saved, for the truck can maintain a steady speed over the entire distance and keep it up for many round trips, while horses naturally tire.

As an example of the time saved in using trucks for delivering fruit the following experience was related by one of the owners of the Harrison Nurseries, of Berlin, Md.

"We use our trucks in transporting fruit, particularly peaches, from orchards to our packing plant. Peaches must be handled quickly, and it is also important that we make our schedule with the railroads. At packing time we employ from 100 to 125 people, whose work is directly dependent upon our trucks. Recently one of our motor trucks enabled us to transport a force of men from Berlin to Easton, 75 miles away, pick $16,000 worth of peaches and return in six days. Another of our trucks this season made thirteen trips in one day between one of our orchards and our packing plant, a distance of two miles, carrying 175 baskets of peaches on each trip, besides two other trips carrying employees."

Another peach grower reported that in the old days when he used a team he had to start for market, 10 miles away, between 12 and 2 A. M. and got back toward noon. The trip with the wagon had to be very slow to prevent bruising. Now, however, with an auto truck equipped with good springs, shock absorbers and pneumatic tires, the most delicate peaches are carried into market within an hour, and other stuff in half the time. He starts out at 5 A. M., is unloaded at market by 6, and is back at the farm a little after 7, with the whole day ahead of him for other work.

Motor trucks not only enable the fruit grower to haul his crop in less time, but he can haul a great deal more to a load than with any other mode of conveyance. This means that in many cases the truck will handle in one load what would have been two or more loads with a team, and in this day of labor shortage this is an important advantage.

California is a great fruit country, and there are some very good roads there, so it is to be expected that motor trucks should readily demonstrate their carrying capacity there to the best advantage. There are hundreds of examples of enormous loads of fresh fruit hauled from one point to another in California, but a representative one is the experience of a Santa Clara orchardist who hauled, on a motor truck and a trailer, 16,000 pounds of fresh apricots from his orchard to the cannery, a distance of six miles. A part of this haul was made over the soft ground of an orchard before the county road was reached, but this outfit operated throughout the picking season and never gave any trouble.

Throughout the various fruit districts of California motor trucks can be seen engaged in doing all kinds of work from hauling manure to fertilize the soil to hauling the fruit crop to market. Many owners have several types of bodies for their trucks, so that they can

**A gang of moldboard plows at work in a California orchard, preparing the ground for a cover crop that conserves the moisture and furnishes a rich supply of fertilizer when ready to be plowed under**

## Cover Crops for Our Orchards

**By H. A. Crafts**

THE use of cover crops in California orcharding is very important to successful culture, and its value is being better appreciated the more it is practiced. Climatic conditions are among those entering into the problem. The rainless summers of California render conservation of moisture very essential to the production of any crop whatever. And it is just as essential to a full fruit crop as to any other.

Cover crops may be made to conserve moisture in more than one direction.

Shading, mulching, and cultivation may be mentioned as being among these.

The benefits of cultivation, of course, accrue automatically. You cannot very well raise a cover crop without first plowing the ground, harrowing, cultivating, disking it; and all this stirring of the soil tends strongly to conserve moisture. Well-plowed and cultivated ground lies in the best shape possible to receive, retain and distribute the moisture resulting from current rainfall. It also stimulates the rise of the hidden moisture, stored in the sub-strata of the soil. Thus it aids the accumulation of necessary moisture from two opposite directions, and thus seems to exercise a most valuable and well-ordered function.

Again, a cover crop provides a very feasible method of refertilization. For the crop, in its state of fullest maturity, may be plowed under, and made to supply that very necessary substance to the soil, known to science as humus, but which in plain, unvarnished English means simply vegetable matter in process of decomposition.

The ancient illusion under which some orchardists labor, even at this late day, that a fruit tree that once germinates, springs up, flourishes and produces fruit, is a permanent institution; and that the principal duty of the orchardist is simply to harvest a crop of fruit, year by year, from these permanent trees, seems to be slowly vanishing from pomological psychology. The truth of the matter is that the fruit tree should be nursed and nourished and fostered even much more faithfully than a mere annual crop of corn, or potatoes or beans. This because the fruit tree stands guard ceaselessly, night and day, summer and winter, in sunshine or rain, being exposed to the constant play of the elements, the assaults of disease and pestiferous insects, and so forth.

The life tenure of the peach tree, the orange tree, or the plum tree is perennial, while that of the stalk of corn is only annual. The stalk of corn germinates, takes root, springs up and flourishes only through the brief period of a seasonal career. About September it has finished its cycle; the farmer comes along with a corn cutter, and the whole life of that stalk ceases, save in the golden kernel which it bestows upon the

# A Railroad to Hudson Bay!

## New Resources in Wheat and Copper That Are Expected to Contribute to Its Support

By Anthony M. Rud

Rebuilding the bridge at Armstrong Lake, destroyed by storm

TWO lines of steel are piercing the heart of the Land of Lobstick and Lode, that musky wilderness stretching north from the Saskatchewan River which since the advent of the white man in the seventeenth century (1670, reign of Charles) has been sacred to Esquimaux, Indians, trappers and traders. The railroad, starting from Le Pas at the junction of the Saskatchewan and Opasquai Rivers, already has driven 359 miles northeastward. Eighty miles more of track, which will be completed before midsummer of 1921, will reach the northern terminus at York Factory (Port Nelson) on Hudson Bay.

A "chechako" in the fullest sense of the word, I have just returned from a journey along this new road, and a trip by paddle and portage over the portion of the right-of-way yet incomplete. If it were not for two very definite reasons I should consider the enterprise the acme of the Quixotic, for no more wild and desolate wilderness exists anywhere between Fort Good Hope (Arctic Circle, long. 130) and Winnipeg, between Halifax and Prince Rupert.

A Canadian wizard of wheat recently has added, to the striking achievements of inventing Kitchener wheat, Improved Marquis, and several lesser varieties, an absolutely new variety of red wheat known as Red Top. With Red Top he has established a world's record of 84 bushels to the acre on his quarter-section experimental farm near Prince Albert, Saskatchewan. This is not the most important quality of Red Top wheat, however, nor is the fact that red wheat always has been the favorite of the flour millers. Red Top matures from ten to fifteen days before Kitchener, Marquis, or any other northern wheat!

The significance of this may not be apparent at first glance to the non-agriculturist, but the story is brief. Frost draws a very definite line in the matter of grain cultivation. One cannot grow wheat north of the line where frost appears before the crop is ripe. Red Top, maturing an average of twelve days earlier than any other variety of wheat, pushes northward the boundary of Canadian wheat lands by at least 125 miles! As wheat is practically the only important crop of northern Canada, it is manifest that the addition of 200,000 square miles or more of fertile land to that territory raising the world's food supply, is a matter transcending in importance what Italy does in regard to Fiume, what the Japanese and Californians decide about immigration, or what the trend of United States' policy in regard to the League of Nations becomes under the new administration. The world must eat.

The relation of this discovery—the result of seven years of continued experiment—to the new Hudson Bay Railway, becomes immediately apparent. For a decade export wheat has been tied up, and made unprofitable at Montreal because of car shortages, vessel shortages, and the piling up of demurrage charges. The Canadian Government, in building the new road from La Pas to Port Nelson is planning to ship *via* Hudson Bay all of central and western Canada's wheat destined for export, thus relieving forever the congestion and obviating the delay. Wheat from the old areas—not even considering that which will be grown on the new 125-mile zone—will be shipped at a saving of from six to fifteen cents a bushel. Seven cents will be the lowest saving on Red Top in the added wheat area.

The figures are plain. The new route will save—outside demurrage charges for delay—the cost of shipping 547 (net) miles from Winnipeg, 650 miles from Regina, 685 miles from Brandon, 1,188 miles from Edmonton, and 1,311 miles from Prince Albert. Each of these cities ships more wheat than all other commodities combined. In the present time of freight car shortage it is not necessary to dwell upon the importance of having thousands more of cars at the disposal of the public; this means the erasing at one sweep of dozens of transportation tie-ups and alibis.

The new wheat zone *must* ship *via* this route, as the net saving in distance varies from 100 to 225 miles more than that mentioned in the above figures.

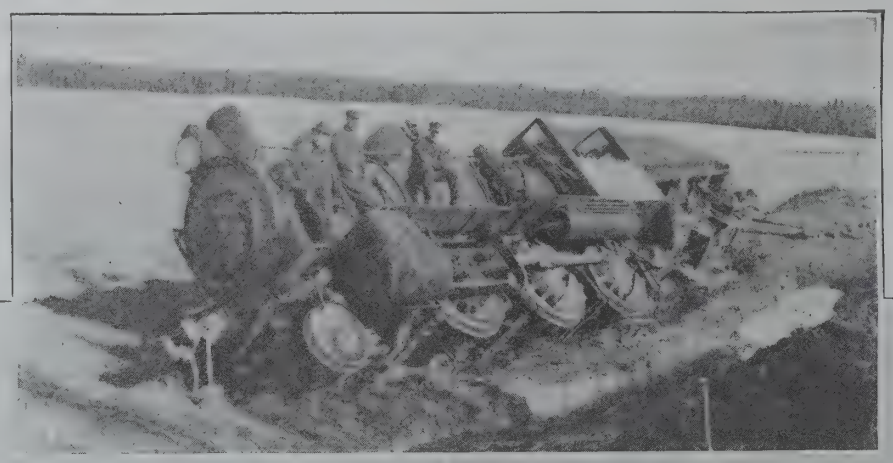
If the new railroad had no other mission it would be of immense importance. As a matter of fact, however, it opens a means of transportation for ore to one of the richest mineral districts in the world.

Herb Lake, Schist Lake and the Flin-Flon region are merely three of a dozen copper, silver and gold properties that are producing right now in prodigal fashion. While the gold and silver as yet have not been discovered in quantities that fade out the Yukon and Cobalt districts, they are being mined with great profit.

Some of the world's richest copper mines, however, lie in the Flin-Flon district. In the States they talk with awe in their voices of Anaconda and other properties which yield from 1.25 to 6 per cent copper ore. *There exist today a half-dozen mines north of Le Pas which are producing ore that yields from 18 per cent upward!* The record, so far as I know, is 21.4 per cent, but the probability is strong that the future will produce even greater yields.

True, there has been grave difficulty with the disposal of mined ore. So far it has been carted overland to Trail, British Columbia, for smelting, and thence clear to Elizabeth, New Jersey, for refining and sale. The new railway, however, will cut out at one swoop half of the expense. A fair fraction of the remainder will be done away with in two years, when smelters and refining plants are erected.

*THE enthusiastic Canadian map-maker has for some years drawn on his charts a dotted line representing a railroad "projected" to give the great inner stretches of the Northwest Territories an outlet to Hudson Bay. But those of us who visualize the northern half of Canada as a land of almost perpetual winter, and Hudson Bay itself as choked with floating icebergs, have always found it difficult to take this "project" seriously. Mr. Rud does not try to disabuse us of any mistaken notions we may have had regarding the summer climate of Canada and the navigability of Hudson Bay—he probably feels that if we don't know about these things we ought to. He does tell us, however, a few things that are news because they are really new, and that have a very large bearing upon the probability of successful operation of the road that is now actually being built to the shores of Hudson Bay.*—THE EDITOR.



1. Starting a portage at Grand Rapids, with the only resident horse north of 55°. 2. A grading difficulty at the present end of the line, Mile 359, north of Le Pas, where the embankment gave way beneath a locomotive. 3. Taking advantage of a breeze on the Nelson River to complete the last lap of the journey to tidewater under present conditions.

**Some glimpses of the country through which the Hudson Bay Railroad will go**

## Boating Without Oars

FROM Germany comes the accompanying photograph, showing a new method of propelling a rowboat. Instead of the conventional oars, this boat is provided with an elaborate system of levers terminating in paddles. By working a lever back and forth, these arms cause the paddles to push the boat along. The paddles may be worked by child or adult, and the operator may sit facing forward or backward, according to his or her preference in the matter.

Copyright Kadel & Herbert

**Working the hand lever back and forth propels this boat along at a good clip**

## A New Deal for the Monoplane

AS far as the large passenger-carrying airplane is concerned, the idea that the biplane is the only satisfactory type has been permitted to go unchallenged in most countries. Monoplane design for small, fast machines and biplane design for the large, slow machines, has been the general formula.

But we have not reckoned with Herr Fokker of wartime fame. This veteran Dutch builder of Germany's best fighting machines now comes forward with a passenger carrier of monoplane design which is just as different from anything else as we would expect from a man who has always arrived at his remarkable results in his own individual way. The latest Fokker creation, which is shown in the accompanying illustration, is the type "F-11," built in the new Fokker works at Amsterdam. This machine is one of two monoplanes to be used on the Amsterdam-London air service, which will ultimately be linked up with the service to Bremen, Hamburg and Copenhagen.

The machine is a monoplane of the cantilever type, with a wing that is very thick in the center and tapers toward the tips. The covering is of three-ply wood, which, if not too heavy, should prove very serviceable in this instance. The large wing is placed on the roof of the cabin, and is held in place by four bolts only, one on each side at the top longeron, and at the apex of each set of three struts running from the bottom of the fuselage. Balanced ailerons of small area are fitted to the tips of the wing.

The plane carries six passengers in the passenger cabin, which is entirely enclosed, while a seventh is carried in the pilot's cockpit in front of the cabin. The power plant consists of a 185-horse-power engine driving a tractor screw. At present the maximum speed is about 90 miles per hour, while the cruising speed is about 75 miles per hour. The tank capacity is such as to give the machine an endurance of ten hours at cruising speed, with which amount of fuel there will still be sufficient disposable lift to carry pilot and four passengers. In a recent flight from Amsterdam to London this machine traversed the distance in three hours and consumed less than 30 gallons of fuel. This is an economical performance and speaks well for the commercial possibilities of Fokker's peacetime carrier.

**Fokker's latest creation—a six-passenger-and-pilot monoplane for use between Amsterdam and London**

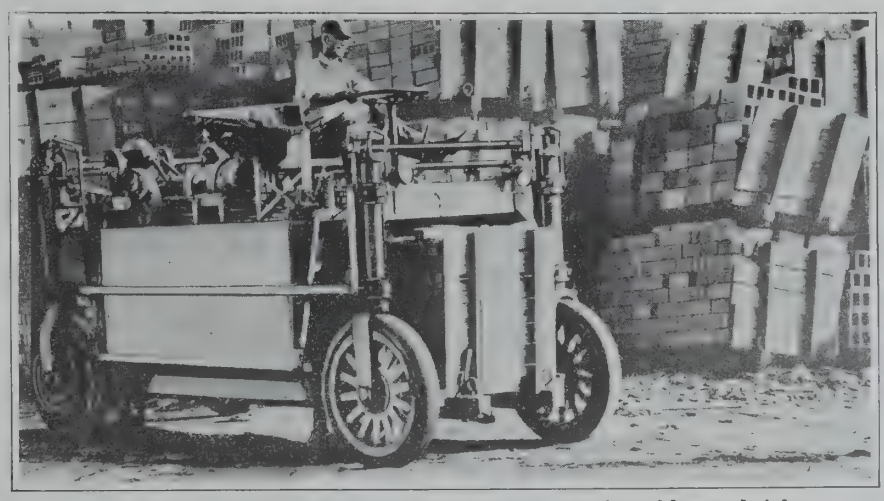
## A New Thought on the Handling of Bricks

AT last we have with us a machine that bids fair to cut building costs. It will save the work of many men and effect big savings in materials that have heretofore been wasted. This carrier was originally designed to cut handling costs in the lumber industry. As such it proved a big success. Such machines are driven by one man sitting on top, from which position he controls all movements. In the lumber yard or mill, the carrier runs over a load of big timber, placed on blotters, picks up the load automatically in a few seconds, and is off again at a ten-mile-an-hour gait to any part of the yard. On reaching its goal it drops its load just as quickly.

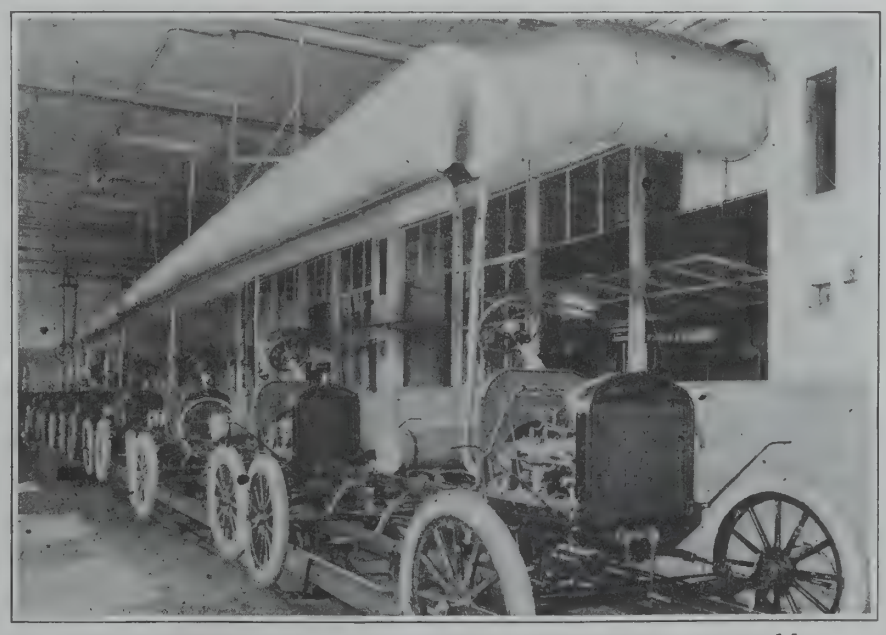
Recently four of these carriers were placed in service by a southern brick company for a most unusual way of handling brick. As such they have proved a marked success. Each of these machines loads itself and carries and discharges automatically 2,000 bricks or nearly 5½ tons to the load, without breaking a single brick, and with a competent operator will pick up or discharge a load in less than eleven seconds.

The brick is located about thirty-five miles across Lake Pontchartrain from New Orleans. These bricks or tiles are placed in crates, 1,000 to a crate at the kiln or plant, after which they are picked up by the carrier which straddles two of these crates and brings them down to the wharf where they are loaded in barges by means of steam cranes. They are removed in the same manner at the brick wharf in New Orleans.

From the wharf they are again picked up by the carriers and deliveries are made by them direct to the buildings under construction without removing the bricks from the crates or rehandling in any way. Aside from the labor-saving feature and faster deliveries, contractors prefer to have the bricks delivered by these carriers as the loads are placed in neat piles at the building and do not take up so much street room. Another very important feature is that the loss sustained through breakage in having trucks dump the bricks in the street has been practically eliminated. In many instances these crates are hoisted to the floors on which bricklayers are working, instead of by the familiar hod-carrier method. As each crate contains a thousand brick, one can readily picture the convenience and savings which this new method of handling accomplishes in the brick and building industries.



**Lumber-carrying truck doing service as a carrier of heavy brick**



**The carbon monoxide fumes from these automobiles are removed by the suction system overhead**

## Artificial Wool from Cotton Waste

ANNOUNCEMENT has been made that a process has been discovered by which artificial wool can be produced from cotton waste. The basis of the artificial wool is cellulose acetate, and the material is claimed to be an even better insulator against heat and cold than ordinary wool to wear equally well, and to take with equal success a dye of any desired color.

The new material has, it is understood, been subjected to severe tests by the textile department of the Leeds (England) University, where it has been successfully converted into fabrics. Cloth was woven with a mixture consisting half of artificial wool and half of natural wool, the product resembling tweed. The cloth, according to Prof. A. F. Barker, head of the department concerned, would prove serviceable for men's wear or for wear by women who fancy cloth resembling homespun.

Prof. Barker declares that artificial wool will have results corresponding to those of artificial silk, but pure wool will not be ousted from the market any more than pure silk has been. It cannot be assumed that people will prefer fabrics of artificial wool to those of natural wool. The artificial wool, however, should be much cheaper than natural wool, and it may be found to have wearing qualities which will commend it to the workers. The *Overseas Daily Mail* states that it is recognized that the new product has certain limitations, one of which is its liability to break and its inelasticity. Owing to this it may not at present be possible satisfactorily to use it in the production of yarns on the worsted principle, for which purpose it is necessary for yarn to possess a uniforming combing length of 2 inches or more. Where short fibers can be employed, however, such as in woolen yarn and cloth manufacture, it may prove serviceable.

## Keeping the Automobile Exhaust Under Control

THE dangers arising from inhaling carbon monoxide gas, even in greatly diluted form, have been pointed out so often and so strongly of late that they are a matter of common knowledge. It is well known that an automobile, operating in a closed garage, generates dangerous fumes which are apt to prove fatal to those working in such close confinement.

With these facts so well established, we can turn to the accompanying view with a greater sense of appreciation for what one of our leading automobile manufacturers has done. Here is the final assembly line where the automobiles are given an engine test. To protect the health of the workers, specially-constructed pipes are attached to the motors and rise to join the suction system above in the manner of trolley poles. The pipes connect with the suction system by means of soft rubber strips which form a flexible channel, as shown. In this manner a satisfactory connection is effected.

# Items In Brief

*A Department Devoted to Current News in All Fields of Pure and Applied Science*

## *Power and Fuels*

**Natural-Gas Gasoline.**—The natural-gas gasoline industry has made large contributions to the supply of motor fuel and has achieved remarkable advances since its beginning. In increasing the supply of motor fuel natural-gas gasoline is a direct means of conservation in that its extraction does not destroy the gas in which it is contained. Experiment has demonstrated that the extraction of gasoline from natural gas does not reduce appreciably the value of the gas for heat, power, and light, but that it is a benefit, for it removes not only the water but also the gasoline, which causes leakage by disintegrating the rubber gaskets in the pipes. Statistics covering the eight years from 1911 to 1918, inclusive, show that an estimated volume of 1,145,113,000 cubic feet of natural gas was treated during that time in the manufacture of gasoline and that the total quantity of gasoline obtained was approximately 755,497,000 gallons. After finishing this supply of gasoline, the natural gas treated was sent through transmission lines to distributing companies or direct to the consumers and utilized for fuel and light. The industry may therefore be compared favorably with the carbon-black industry, in which the natural gas is destroyed.

**Chinese Coal.**—According to A. M. G. Grant, a consulting mining engineer who recently returned to Great Britain, 100,000 tons of coal have been shipped as an experiment from China to Newcastle-on-Tyne. It is said that the coal is "of excellent quality, and, imported in larger quanties, could be sold at cheaper rates than British." All of which is certainly strange!

**The Fallacy of the Smokeless Chimney.**—Year after year we have been taught to consider the smokeless chimney as a symbol of furnace economy. Yet along comes J. T. Beard in a recent issue of *Power*, with the bald announcement that in a coal-burning plant a stack that is smokeless all day indicates excess of air supply. The author points out that the loss due to unburned combustible in smoked chimneys is probably not more than 1 or 2 per cent of the heat in coal and this is more than balanced by the loss due to excess air in the smokeless chimneys. The real objections to smoke are: First, the sooting of heating surfaces, and this trouble can be taken care of with soot blowers; second, interference with the health and comfort of the community. Mr. Beard concludes that in a well-designed plant it is possible to have a smokeless stack as well as economical plant by providing proper combustion space and correct furnace design.

**Something New in Steam Generators,** known as the Blomquist steam generator, is described in a recent issue of *Electrical World*, in the form of an abstract from the German technical press. The generator in question is a boiler, or high-speed steam generator, of a radically new type, which has been put in operation in a Gothenburg mill. The boiler consists of 11 pressed steel cylinders of 12-inch diameter and 8 feet heated length, which are rotated at the rate of 375 r.p.m. Due to the centrifugal action the water will cover the entire inner surface of the tubes, keeping the temperature of the steel below 300 deg. C. The tubes are supported in ball bearings, feed water being injected at one end and steam taken out at the other, through steam-tight boxes. The generator produces 13,000 lbs. of steam per hour at 50 atmospheres or 740 lbs. per square inch. This steam generator may be used to increase the pressure in existing plants, where high-pressure turbines can be employed to utilize the increase in boiler capacity thereby obtained.

## *Automotive Progress*

**Britain's Motor Signals.**—It is reported that it will "shortly be made compulsory" for uniform road signals to be used by drivers of all vehicles in Great Britain. "The signals are to be made by either the arm in the case of right-hand-drive cars, or by a mechanical arm in the case of left-hand-drive vehicles," and, as a commencement, they will comprise: Raised arm, "Stop." Horizontal arm, "Turn to the right." These signals must be given from the right-hand side of the car. In London additional signals will be brought into use. It is added that the use of the left-hand-drive car may be affected. "Although the actual type of mechanical signal necessary in this case has not yet been selected, it will probably be found more convenient to use cars fitted with the right-hand-drive than to install a device which cannot for some time be reliable." In interpreting all this, we must of course remember that Britain keeps to the left.

**Automobile Bodies by Electro-plating.**—In a recent issue of the *Automobile Engineer* there is described a novel process for making metal panels for automobile bodies. The process is an electrolytic one, in which a mold is provided of the desired profile and is rendered electrically conductive; also a member which operates with it in such a manner that when placed together they form the walls of a vat, and constitute the anode and cathode members. When electric deposition is completed, the finished article is removed from the pattern, and the operation can again be repeated upon the latter. One wall of the vat is made of the metal which it is required to deposit, and it is insulated from the cathode member. Special means are provided to secure an even deposition of the metal; the vat is sealed and an upper tank is provided to contain the electrolyte, a constant vigorous stream being maintained.

**Our Motor Fuel Situation.**—The number of automobiles in service increased about 1,700 per cent from 1909 to 1918, while the production of gasoline increased 560 per cent, and the production of crude oil only 95 per cent, according to the Bureau of Mines. Because of the great demand for kerosene, it is unlikely that the quantity of gasoline can be increased by making it less volatile than now. The extraction of gasoline from natural gas is approaching its maximum. The supply of fuel oil from which gasoline may be obtained by cracking is sufficiently large, although the demand for fuel oil has increased rapidly and the price has more than doubled, but the process of cracking is expensive and would be unprofitable without a further increase in the price of gasoline. The use of alcohol as a motor fuel will probably increase, as well as the use of benzene produced from coal tar.

## *Pure Science*

**The International Congress of Mathematicians,** which recently met in Strassburg, decided to hold the next congress in New York in 1924.

**A Remarkable Coal Mining Laboratory** has been installed under the science and engineering building of the Carnegie Institute of Technology at Pittsburgh. The laboratory comprises a full-size coal mine, a mine locomotive and a complete set of coal and metal mine machinery, furnished by various manufacturers.

**Agricultural Experiment Stations in Alaska.**—The U. S. Department of Agriculture maintains five agricultural experiment stations in Alaska; viz., at Sitka, Kodiak, Matanuska, Fairbanks and Rampart. The last named is just under the Arctic Circle, where the temperatures range from 88 above to 63 below zero Fahrenheit. These stations, says an announcement from the department, have done considerable work in breeding and establishing new varieties of grains, berries, fruits and other economic plants suited to the short season of growth, and have also promoted the raising of domestic animals, of which there is great need in Alaska on account of its remoteness from the rest of the world. At present the largest farming settlement is in the vicinity of Fairbanks, in the Tanana Valley, raising 5,000 bushels of grain in 1919.

**The Death of Dr. Margules.**—Mr. Fitzhugh Talman's appeal in behalf of the Austrian meteorologists, recently published in our correspondence column, is reinforced by the statement that has appeared in the London *Times* that Dr. Max Margules, well known for his brilliant contributions to dynamic meteorology, died of starvation in Vienna on October 4. A warm tribute is paid to Margules in a current number of *Nature* by Dr. Ernest Gold, of the British Meteorological Office. Margules published in 1892 and 1893 a series of masterly papers on the motion of air on a rotating spheroid, and in 1903 he published a remarkable memoir on the energy of storms. In recent years he had retired entirely from meteorological work and up to the time of his death had been striving to live on a pension of 400 crowns a month, which is equivalent to less than two dollars. The American Meteorological Society is raising a fund in behalf of the meteorologists of Austria and their families, and has already begun to remit food drafts. Contributions can be sent to the secretary of the society, Dr. C. F. Brooks, U. S. Weather Bureau, Washington, D. C.

## *Transportation*

**How Railroads Handle Coal.**—The Norfolk & Western Railway Company has contracted for another car dumper which will have a tremendous capacity. This machine will take the largest road cars and overturn them into specially designed motor-driven transfer cars having power-operated bottom gates through which the coal will be distributed to the lines of coal-loading bins on the piers. The vessels coming alongside the piers will then be loaded rapidly by gravity with breakage of the coal reduced to the minimum. Mechanical trimmers, which effect a wonderful saving by eliminating hand trimming, will be used. Could the road cars be supplied without interruption, this machine alone would have a capacity for loading into boats over 8,000,000 tons of coal per year when operated for eight hours during each working day. This represents 1,440 ocean-going vessel cargoes.

**Fuel Oil for Locomotives.**—At the annual meeting of the International Railway Fuel Association at Chicago, some interesting figures were presented relating to comparisons made on the Santa Fé system where one-half of the locomotives have been constructed or converted to burn oil. The fact was brought out that the life of a boiler fired with coal is about 10 per cent greater than one fired with oil, while the life of the tubes is about 40 per cent higher in the coal burners.

**Railway Fuel Conservation.**—According to the *Railway Age*, the conclusions reached regarding fuel conservation are that this conservation depends upon efficient education of the whole of the railroad staff rather than confining it to the train crew, and the provision of a constant stimulus to maintain their intensity of interest in the subject by friendly competition and public spirit. Some other phases of the subject, such as economical speeds, facilities for adequate train housing and repair, selection of the best types of locomotives for specific roads, and train despatchers' duties are referred to, all of which are stated to be contributory factors in fuel conservation.

**Chinese Railway Standardization.**—Although it would probably be economically impracticable for one nationality to furnish and equip China with the extensive railway mileage necessary for the development of the country, it has been pointed out that the advisability of maintaining an adequate staff of American technical experts on the Chinese Railway Standardization Commission, as well as the expediency of offering facilities for the training of Chinese engineers in this country, are evident in the light of the opportunities for renewals and extensions of equipment by American manufacturers accruing from the establishment of American standards on the Chinese railways.

**A New Oriental Line.**—The steamer "M. S. Dollar" sailed from Vancouver on October 22 for the Orient, inaugurating on this voyage a new line of Oriental commerce. She has been fitted up with refrigeration machinery and has a capacity for 300 tons of frozen produce. This space will be used to ship Chinese fresh game, eggs, and meats to New York by direct steamer. If the venture proves successful other vessels of the Canadian Robert Dollar company will be fitted up with refrigeration holds. The ship will carry butter and other American dairy products westward. She operates on the triangular New York-Vancouver-Orient service.

## *Communication*

**South African Radio.**—The Union Government has acquired the station at Windhuk, which was erected by the Germans and which originally was powerful enough to communicate with Berlin. This station will be put in order in the near future and will be one of the best equipped stations in the world. The

Windhuk station will be working with Oxford *via* Nairobi and Cairo, the scheme providing for stages of 2,000 miles each, transmission over which distance is assured. This will no doubt greatly relieve the ocean cables between South Africa and England, which are now unable to cope effectively with existing traffic.

**Improvements in Arc Generators** are described in a recent issue of *Wireless Age*, especially as concerns the Poulsen type. For purposes of coil insulation it has previously been considered essential to place the magnet windings in the lead from the generator to the arc electrode which is grounded, and with this arrangement it is inadvisable to ground the frame of the direct-current generator on account of the danger of burning out the generator insulation. L. F. Fuller, who has made many improvements on the Poulsen arc, finds that by combining the choke and magnet coils and placing them in the lead connected to the antenna side of the arc, and by grounding the generator side of the arc to the generator frame, a better and cheaper construction is possible, and the generator is safer to handle. Usually, but not necessarily, the negative lead is connected to the grounded side of the arc.

**Fading of Radio Signals.**—A detailed study of actual cases of "fading" or fluctuation in the strength of signals occurring in the area of the Persian Gulf and the Red Sea is given with the aid of maps and sections of intervening mountain ranges in a recent issue of the *Wireless World*. From the results of his observations the author expresses the opinion that these effects are entirely due to the differences in altitude of the intervening country, and he puts forward the theory that the intercepted wave does not pass to a considerable height (probably not more than one or two miles) above sea level, but that the maximum height attained increases with the distance, so that the less the range the nearer the semi-parabola of its course approaches to a circular arc.

**A Worthwhile Tube Transmitter.**—In a recent issue of *Telefunken-Zeitung* there appears a description of a ten-kilowatt transmitter employed at the Nauen station, using a battery of 30 tubes of 500-volt rating. The method of connection is described, and the method of operating. It is stated that this installation gave much trouble at first, but that the difficulties, mainly connected with the generation of oscillations of very high frequency, were gradually overcome. There is reason to expect that it will be possible to construct 10-kilowatt tubes and connect them in parallel so as to attain outputs of 500 to 1,000 kilowatts.

## *Electricity*

**Oil Switches for Heavy Currents** are generally accompanied by difficulties in dealing with large outputs. The electrodynamic effects which arise with very heavy currents are the most serious source of danger. The very heavy current-rushes exercise both thermic and dynamic effects on the whole installation, and are most difficult to control by any preventive method, short of the predetermined artificial limitation of the short-circuit current. The value of this should not exceed 50,000 effective amperes. An authority states that if this limit is not exceeded, the process of opening a switch is more serious than that of closing it.

**Safety Panels in Sections** for residences, apartment houses, office and public buildings are now coming into general use. Metal sectional covers enclose the switches and bus bars, the switch buttons and plug fuses alone being exposed. This gives full protection to the operator against contact with live parts. Should it be necessary to replace a damaged switch, the sectional cover can be removed and repair made without disconnecting the wires, exposing other switches, or removing the panel from the box. The ensemble is a strong, compact panel of excellent workmanship and attractive appearance.

**Foot-Operated Switch for Foiling Holdups.**—The crime wave which has swept through many of our leading American cities of late has inspired John C. Rundback, a jeweler of New York City, to invent a novel form of foot-operated switch. This device consists of contact-making units arranged in the form of a long strip, and installed along the bottom of a counter or desk. In the event of a holdup, the victim can press any part of the contact-making member with his foot, thus closing a circuit and operating any given apparatus. The circuit may be used to ring a bell outside the store, turn in an alarm to the nearest police station, drop a steel curtain between the victim and the thieves, or for any other purpose. The contact-making member may even be arranged along the edge of the counter or along a wall, so that it may be depressed by leaning against it. At any rate, this novel switch arrangement may be operated while obeying the command of "hands up" and without arousing the suspicion of the bandits.

**Locating Buried Conductors.**—A long-buried conductor, for instance a cable or a pipe line, will tend to direct and concentrate electromagnetic waves traveling over the ground where the conductor lies buried, according to *Electrical World*. This is utilized for determining the location of such conductors in a method patented by a German radio company. A big coil antenna excited from an ordinary spark station on a motor car serves as a transmitter, and a similar coil antenna is used for receiving. The two antenna frames are carried along the ground, and the man receiving the message has to direct the carriers till a maximum sound is heard in his headphones. A wave length of 1,500 meters is employed, and using a 200-watt transmitter, the antenna frames must be kept 40 or 50 feet apart to avoid direct induction. Even a thin lead-covered single-pair telephone cable 5 feet or 6 feet deep could be located within a few feet by means of this outfit.

## *Mechanics*

**Getting Along Without Hand Filing.**—A German company has introduced a milling tool which produces a finished surface equal to the best obtainable with hand filing. The cutting edges of this machine are similar to those of a file, but arranged spirally so that it is only necessary to press the work against the revolving cutter in order to get a true surface. The machine will cut through the mill scale of rolled sections and polish them bright in a remarkably short time. It will similarly cut through a crust of castings and give a bright smooth surface. It is conceded that a mechanic with a new file can cut one-fifth oz. of filings from a rough casting in a quarter of an hour, while the new machine will cut better than 17½ oz. in the same time from the same casting. What is more, the cutting member of the machine is said not to clog, and can therefore be used for a number of metals such as lead, copper, tin and zinc, as well as for such materials as hard rubber, slate, marble, celluloid, hard wood, bone and so on, where a file would be more or less useless.

**A High Speed Hack Saw** suitable for manufacturers having quantities of bar stock to be cut to repetition size, and offering a considerable saving in time and labor, has been brought out by a Chicago machine builder. At maximum speed and feed, the new machine will cut six-inch round cold-rolled steel in ten minutes, the resetting of the stock bar after each completed cut being automatic. Bars up to 20 feet in length may be handled and pieces up to 3 feet in length can be cut off.

**How Precision Blocks are Made.**—The general requirements of gage blocks, according to *Machinery*, are: (1) The two gaging surfaces should be true planes; (2) the gaging surfaces should be parallel to each other; (3) the length of the gage should conform to required dimensions and (4) the gage blocks of a set should differ in size by increments, making it possible to obtain any dimension within the range. A special chromium steel is recommended as a suitable material. The steel bars are sawn, straightened and ground, and after being drilled and countersunk are heat treated, again ground and finally sand-blasted.

## *Engineering*

**Canal Project for France.**—Plans are being formulated for the construction of a canal to extend from the port of Dunkirk to the basin of Saarbrücken, permitting the navigation of boats up to 600 tons. The length of this canal will be approximately 600 kilometers (372 miles). The canal will be known as "Le Canal du Nord-Est."

**Poland's Longest Pipe Line.**—The longest pipe line in Poland for the transmission of oil was opened on September 6, 1920. This duct, which runs from Jaslo to Gorlitz, is constructed of 10-inch piping and is 28 kilometers (17.38 miles) in length. It is connected with another line that runs from Jaslo to Mezinek. Both these lines were constructed by the Polish Government and are used for the transmission of oil from the wells in Mezinek to numerous refineries and factories. Since the construction of the new pipe line a sufficient number of factories have begun to use oil as fuel instead of coal to result in the saving of 6,000 carloads of coal per year.

**Why Rails Rupture — and a Cure.** — From the *Comptes Rendus* we learn that a most frequent cause of the rupture of rails free from local manufacturing defects consists in the gradual development of fine fissures on the surface subjected to rolling action. Periodic examination and withdrawal of service rails showing signs of fissuring is the only preventive measure suggested up to the present time. The authors of the article show that the phenomenon is a very general one in materials subjected to intensive superficial work-hardening, and is particularly marked in hard metals such as chilled cast iron and hardened tool-steels. These French authorities suggest that superficial annealing prior to the critical age will rejuvenate rails and prevent the occurrence of fissuring. Such an operation could be carried out readily by means of the equipment mounted on wheels which has been devised for superficial hardening of the rolling surface. Such thermal cures, it is held, would do much to prevent fissuring and prolong the life of rails.

**Concrete Pouring on a Vast Scale.**—We are accustomed to big figures when speaking of modern concrete work. Yet a recent description of a large concrete plant, which appeared in a recent issue of *Engineering News-Record*, is startling enough to bear quoting here. The plant is to distribute 30,000 cubic yards of concrete from two 175-foot towers over an area of 800 feet by 1,800 feet. The elevator of each tower holds one cubic yard and does 30 trips an hour. The greatest length of main chute is 350 feet. Chutes are 12 inches wide and 8 inches deep at a uniform slope of one in three. A novel feature is that the chutes are practically rigid, being supported at 50-foot intervals by timber towers and braced laterally by truss wires over horizontal struts.

**A Forty-Five Mile Aerial Cable Tramway** being constructed in Colombia, South America, is reported to be half completed at this writing. It starts at Mariquita, at an elevation of 1,500 feet, crosses a 12,000-foot summit and descends to Manizales, which is at an elevation of 6,700 feet. The cableway is supported on 437 steel towers, of which 8 are over 130 feet high. The longest span is 3,168 feet. The track cable is a 2⅝-inch wire rope running on 24-inch sheaves. The carriers take normal loads of 670 pounds, traveling at 400 feet per minute. Steam driving plants will be employed as motive power, arranged in 30-horsepower units and distributed among 20 stations. Twenty-one miles of this cable tramway has been in operation since 1916.

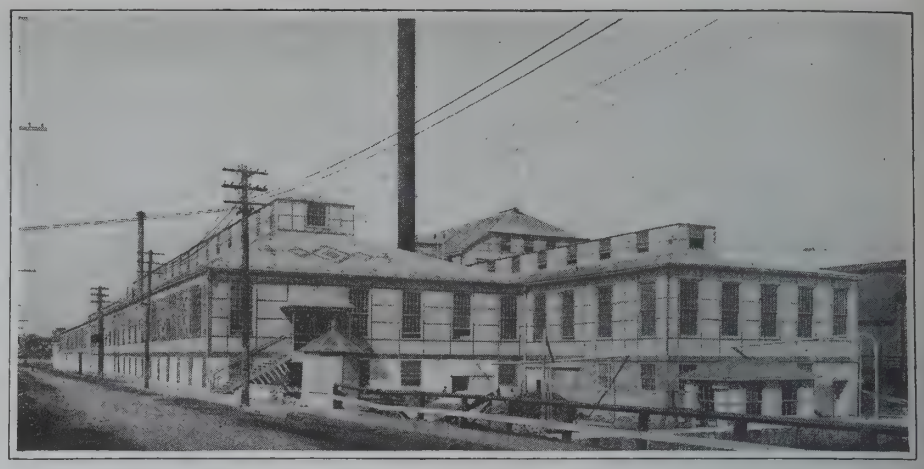
## *Industrial Efficiency*

**American Import Figures.**—The Bureau of Foreign and Domestic Commerce has just published part 1 of "Trade of the United States with the World, 1918-1919." This bulletin gives statistics covering the imports of merchandise into this country, by countries of origin and principal articles, during the calendar years mentioned in the title. For most of the articles included in the table, quantities (in addition to values) are given in the customary commercial units or in weight. This new publication, which is expected to prove peculiarly useful to American importers and merchants, is part 1 of Miscellaneous Series No. 106, and may be obtained for 10 cents from any of the district or coöperative offices of the bureau or from the Superintendent of Documents, Government Printing Office, Washington, D. C.

**Leather from Rabbit Skins.**—According to American Consul Norton of Sydney, Australia, a secret process, said to be unknown hitherto to the tannery trade, has been discovered by an Australian for making leather from rabbit skins and recovering the fur as a by-product in felt making. A company has been formed in Sydney to turn this discovery to practical use, having established works capable of handling about 100,000 skins a week. The leather has already been utilized in Sydney in the manufacture of boot and shoe uppers, hand bags, gloves, and other articles.

**Remitting Customs Duties to Develop Mines.**—The Vancouver Board of Trade is endeavoring to assist development of the mineral resources of the province in a manner that should prove very satisfactory to United States manufacturers of mining machinery. The mining bureau of the board has recommended that the organization approach the Dominion Government asking that customs duties on mining machinery imported from the United States to the mines of British Columbia be remitted. Though British Columbia metal manufacturers are not wholly in sympathy with this proposition they have expressed themselves as willing to assist the board in the effort if it is modified to such an extent that it will not work an actual unfairness to them.

House externally protected from fire and weather by the liberal use of asbestos shingles



Asbestos shingles cover the roof and asbestos building lumber cloaks the sides of every building in this plant

# Asbestos in Architecture

## The Growing Importance Played by This Fibrous Substance in Modern Building

By Robert G. Skerrett

WHY asbestos is what it is the man of science cannot tell. He cloaks his ignorance by calling it a fibrous, hydrated silicate of magnesia, and then, looking wise, expects you to be satisfied. Despite the fact that Nature has kept her secret well, still day by day, comes a growing realization that "mineral flax" is serving increasingly useful purposes. Here in the United States the demand and the fields of application are widening at an impressive rate, and presently even the layman will ask, "How could we get along without the stuff?"

Back in the dim days of this planet's formative period, eons and eons before human kind conceived even elemental notions of economy and safety first, asbestos was stored in the veins of the earth's rocky crust to await the time when man's proper fear of fire and a keen desire for saving in a number of directions should make him cast about for a raw substance which might serve these ends either directly or indirectly. And now asbestos is robbing the flame of much of its menace, and the same material is conserving both heat and cold which primarily owe their intensity to the consumption of coal. Probably nothing is more suggestive of these efforts to arrest the fleeting dollars than the way in which asbestos products are figuring in modern architecture.

Here in the United States the annual fire loss totals more than $250,000,000, and the startling fact about this wastage is that most of it is a needless sacrifice. Because of this tribute to the flame insurance rates rise proportionately, and for our heedlessness we trace the "wicked circle" of added outlays. The wooden shingle is so often tinder to the chance spark; and the frame building and timber structures generally can offer but a feeble resistance to fire. Aside from this inherent fault, woodwork exposed to the weather is more or less perishable, especially if not painted or otherwise subjected to a preservative treatment.

But structural metal in the cases of roofing and various forms of sheathing is all too frequently no more enduring than wooden shingles, clapboard, and the like. Heat and cold, moisture, oxygen, and atmospheric impurities attack the iron, steel, copper and tin and bring about their oxidation and disintegration. Paint and other surfacings may suffice if applied at short intervals, but they involve repeated expenditures that represent a heavy offset against any apparent initial savings. Splendidly as wood and metal supply our wants in some directions it is dawning upon us gradually that we need more enduring and fireproof materials for certain parts of our industrial structures, our homes, our office buildings, our schools, etc. Happily for us asbestos is at hand to help out.

Inventive genius and manufacturing cunning have made possible shingles, roofing, siding and "lumber" composed of asbestos or of asbestos and hydraulic cement, according to the service required. The public is pretty familiar with asbestos covering for pipes, but it is only comparatively recently that we have profited by European example and accepted the asbestos shingle as something to be desired. It was only natural, with the ice thus broken, that our business enterprise would soon find other ways in which to work up asbestos and to employ these products to advantage. The pioneer in this evolution was Ludwig Hatschek, an Austrian asbestos worker, who, bent upon making thin sheets or slabs of cement for building purposes, conceived the idea of using asbestos fiber as a reinforcing material. Because of his invention, a single plant in Austria turns out yearly more than 100,000,000 square feet of asbestos-and-concrete roofing in forms susceptible of easy application. The secret of success depends upon the manner in which the asbestos and the cement are combined.

It seems that where the Hatschek process is not followed that the mixing of the material dry and then adding

## The Flyer's Artificial Eye and Ear

**By Dr. Alfred Gradenwitz**

THE flyer's eye and ear are bound to fail him in a fog, in the clouds and by night—the eye, in so far as he no longer detects anything to guide him in the gray uniformity surrounding his machine, and the ear, inasmuch as his sense of direction and verticality, depending on the canals of the middle ear, no longer tells him at what angle his machine is banked.

In the last stage of the World War, all the huge fighters of the German army were fitted with a wonderfully efficient apparatus which could be fitly termed a substitute for the human eye and ear, viz., the Drexler Gyroscopic Steering Gage, which, of course, was developed on lines quite independent of the Sperry instrument. In designing this apparatus, the inventor availed himself of a less well-known gyroscope law. In fact, so far from starting from a "triple-liberty" gyroscope, that is, a top freely rotating in a Cardan suspension, he based his work on a "double-liberty" gyroscope, viz., a top free to rotate round its own axis, and, in addition, in another plane, though the latter rotation is limited by elastic strips or springs. In other words, a top in a Cardan suspension, of which the outer ring is fixed while the deflection of the ring carrying the gyroscope is limited in the manner just outlined.

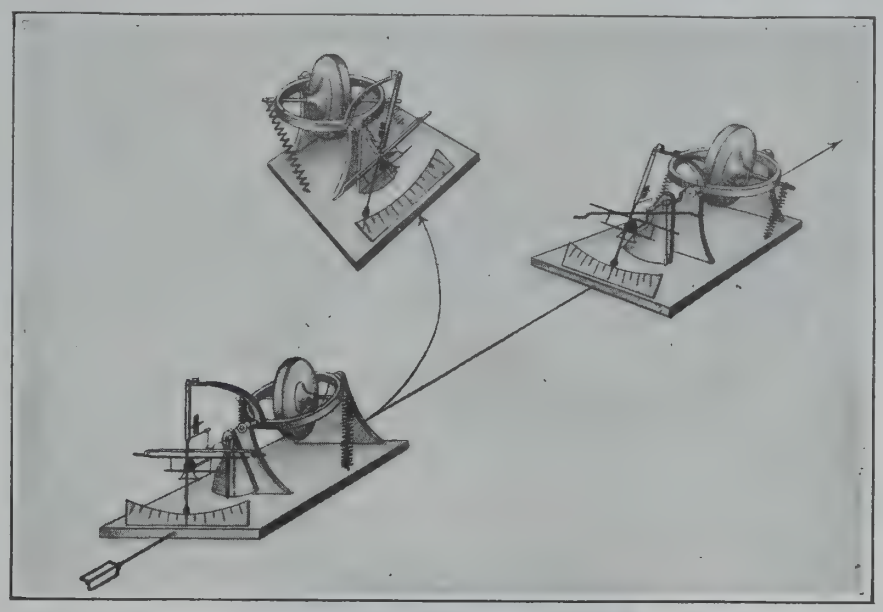
If such a gyroscope be inclined sideways it will not show any deflection, but, on account of the tension of the elastic bands or springs, and the stationary arrangement of the ring carrying the top at right angles thereto, it will readily follow any inclination of the gyroscope.

If, however, the apparatus be turned round in the direction of the arrow, the *law of precession* will come into play; that is to say, the top will respond to any thrust in the direction of the arrow by a rotation at right angles thereto. So far from following the rotation corresponding to its previous position, the top will therefore deflect, overcoming the tension of the elastic bands as indicated pictorially.

A "double-liberty" gyroscope such as this, provided with an index, is so installed on the flying machine that the top, as long as no outside forces are exerted upon it, will rotate in a plane determined by the vertical line and the direction of flight. This top, apart from its rotation round its axis, can only perform a motion limited by springs at right angles to the longitudinal axis of the flying machine. Where the top occupies the position just outlined, the index connected with it will be in its central position, thus showing that the machine is flying straight ahead. If, however, the machine voluntarily or involuntarily describes a curve, the outside frame carrying the top, which is rigidly fitted into the flying machine, will be turned, thus causing the top and the index connected with it to deflect at right angles thereto, to the right or left, according as the curve described is a right-hand or a left-hand curve. As soon as the machine is again flying in a straight line, the springs above referred to will reduce the curve index to its central position.

The gyroscope is combined with a transversal pendulum oscillating in a damping glycerine casing, for indicating any transversal deflection from the horizontal position of the carrying planes, while a specially designed liquid level gage allows even the slightest longitudinal inclination of the plane to be noted. The reading marks of the pendulum should always agree with the upper carrying surfaces of the flying machine phantom, if the machine, in flying either in a straight line or in a curve, is to be in equilibrium. A special readjusting attachment enables the apparatus to be adapted to the peculiarities of the machine or any personal preference of the pilot by allowing the angle of inclination in curves to be increased or reduced at the free will of the aviator.

The use of this steering gage not only means increased safety to the pilot and passengers, but relieves the enormous strain upon the nerves of the pilot, who no longer has to spy about and anxiously to look for his bearings at the ground below him through the fog, clouds and darkness.



**The German double-liberty gyroscope, showing the manner in which deflection of the plane carrying it from the true horizontal affects the instrument**

## Finding a Cool Hat

HOWEVER lightly one may be clad there is little comfort in the hot weather if the hat is not having a cooling effect. In this connection some interesting tests have been made to determine the heating or cooling action of various kinds of hats commonly worn. On a very bright day when the shade temperature was 96.8°F. seven individuals were given hats, each one being of a different type. These were worn outdoors for two hours and at the end of this time the temperature inside the hats was taken.

In the case of a typical soldier's hat, made of cloth and with a hard peak, the reading was very high, being no less than 98.6°F. In an ordinary cloth cap it was 94.1°. Inside the hard round bowler the record was 92.3°. Contrary to expectation the silk hat came fourth on the list with a temperature of 89.6°. The hard straw hat was not very much cooler with a temperature of 86.0°. Very much more comfortable was the soft felt hat with a reading of only 79.7°. It was discovered that, where the felt was black, or very dark in color, the air inside was much hotter than in the case of a light shade. The figures given are for a hat of a somewhat pale gray hue. Coolest of all hats is the soft straw Panama, which gave a temperature of 77.9°.

**How the new system facilitates the installation of wall fixtures; and the outlet plate, ceiling plug and wall plug**

## When a Lighting Fixture is Not a Fixture

**By George Gaulois**

ELECTRIC lighting fixtures need be "fixtures" no longer. Why? Because a device recently invented and now developed on a practical scale makes it possible to move electric chandeliers and wall brackets from place to place as easily as electric toasters, vacuum cleaners and other appliances are plugged in the usual lighting circuit.

The basis of the new invention, which promises to mean much in the electrical industry, is a plug with curved blades. This plug may be attached to any wall light. With its lighting fixture attached, this plug is inserted with a rotary motion into a new type of electric outlet, the blades pointing upward. Electrical and mechanical connections are made at the same time; and the plug, supported by the curved blades, is strong enough to hold the heaviest wall fixture. The outlet looks very much like the familiar baseboard plate, having two parallel slots in a rounded triangular center.

An inconspicuous circular plate marks the new ceiling outlet, which forms a unit of this novel system of fixtures. A plug with curved prongs also is provided for this outlet. It differs from the wall plug, however, in that one-half of the plug is inserted at a time, the prongs extending in opposite directions. A hook at the other end of the plug supports the chandeliers, and makes the necessary electrical connections by means of flexible wires. Now these mechanical hooks, as distinguished from the curved prongs which make the electrical connections and also secure the lower hooks to the ceiling, may be arranged either in a coinciding or in an opposite manner, so as to form in construction either a hook or a ring. In either event the ring of the chain supporting the fixture serves to hold the two halves together, thus locking the entire arrangement in place.

The devices for this new system are to be manufactured by a number of companies and will be on the market by the beginning of the new year. The flexibility of lighting which will be afforded by this system will be especially appreciated in the home. The ability to rearrange and replace lighting equipment without the services of the electrician will make possible a rapid development in the science of home lighting. Builders of new homes will be freed from the necessity of selecting all their lighting fixtures before the house is finished. A sufficient number of outlets provided for in the architects' plans will make it possible to buy lighting fixtures as needed after the house is finished.

## What Is Dry Rot?

THE term "dry rot," the Forest Products Laboratory finds, is applied by many persons to any decay which is found in wood in a comparatively dry situation. Thus loosely used the term actually includes all decay in wood, since wood kept sufficiently wet cannot decay.

In the more limited sense in which pathologists use the term, "dry rot" applies only to the work of a certain house fungus called *Merulius lachrymans*. This fungus gains its distinction from the fact that it is frequently found growing in timbers without any apparent moisture supply; in reality it does not grow without moisture and is as powerless as any other fungus to infect thoroughly dry wood. Given moist wood in which to germinate, it is able to make its way a surprisingly long distance in dry timbers, drawing the water it needs from the moist wood through a conduit system of slender, minutely-porous strands. Wood in the typical advanced stage of dry rot is shrunken, yellow to brown in color, and filled with radial and longitudinal shrinkage cracks, roughly forming cubes. In many instances these cracks are filled with a white felty mass, the interwoven strands of the fungus.

The dry rot fungus is active in nearly every region of this country, in Canada, and in Europe. It is destructive to timbers and logs in storage. Soft woods are more commonly infected by it than hard woods.

## Star Clusters—Their Bona Fides and Their Distances from Us

By Professor Henry Norris Russell, Ph.D.

IN various parts of the sky the stars appear to be grouped into more or less conspicuous clusters. Most of these are visible only with the telescope, but here and there we find one in which the individual stars are so bright, and so widely scattered in the sky, that the character of the group can be recognized by the naked eye. The astronomers of ancient times—who were active and careful observers, so far as the means at their disposal permitted—recognized several of these clusters, and gave them names, which have come down to us, and are still in use. The most conspicuous and the most famous cluster of all is doubtless the Pleiades, which, from the brightness of the stars and their close association, attracts the attention of the most casual observer. Not far away, and also in the constellation Taurus, is the more scattered group called the Hyades—the "rainy stars," because their appearance marked the beginning of the rainy and stormy season in Greek waters. Farther east in the heavens, in Cancer, is a hazy spot, known to the ancients as Praesepe, meaning a sheepfold or a manger. The unaided eye just fails in this case to recognize the individual stars, but a small opera glass shows them distinctly. Eastward again, beyond Leo and to the north, is a scattered group of stars, just comfortably visible to the naked eye, which has been elevated to the dignity of a constellation, Coma Berenicis, or Berenice's Hair.

### Are They As They Seem?

When the modern astronomer comes to consider these clusters, the first question he asks is, naturally, "Are the stars of these groups really near together in space and associated in some way, or do we have to deal with a mere accidental grouping of unrelated stars, some near by, some remote, and looking close together in the sky only because they happen to be almost in line with one another?" For a compact group like the Pleiades, common sense suggests, and calculation confirms, that it is incredible that so many conspicuous stars should by mere chance be crowded into so small a region, with the whole expanse of the heavens available. But for a more scattered assemblage like the Hyades, this simple test is insufficient.

The tale has long ago been told in our columns how Professor Boss, having completed his great catalog of the proper motions of the brighter stars, found that forty stars, in the Hyades and the surrounding region, were moving across the heavens in about the same direction and at almost the same rate. This noteworthy discovery put it beyond question that the Hyades, too, were a real cluster of stars which now are fairly close neighbors in space, and have been so in the past for an indefinite time. What is more, it appeared, on careful study, that the motions of these stars in the sky were not quite in parallel lines, but that they converged toward a definite point, about ten degrees east of the bright star Alpha Orionis; so that if we could watch the cluster for ages, we should see it approach this point in the heavens, and apparently shrink together as it did so. This must obviously be an effect of perspective, arising from a gradual recession of the cluster from the sun. Observations with the spectroscope showed that these stars were actually receding, and all at the same rate—another proof of physical connection. By combining what we know of the apparent rate of motion of the cluster in the sky, and the real rate in kilometers per second, Boss succeeded in calculating its distance, which came out 140 light-years.

Not all of the naked-eye stars in this part of Taurus really belong to the cluster—for example, Aldebaran, the brightest of all, is moving across the sky in quite another direction, and is probably considerably nearer to us than the cluster stars. But these outsiders can be recognized at once by the fact that their motions do not agree with that of the cluster.

A similar community of motion exists among the Pleiades, and is found also in Praesepe, and among many, though not all, the stars in Coma Berenices. It appears therefore that all these groups are real clusters. But there is no other case in which the perspective effect of convergence of the motions has so far been detected—mainly because the other clusters cover such small regions of the sky; hence we cannot apply Boss's ingenious method to determine the distance of any of the other clusters. Success has, however, recently been obtained in the case of Praesepe. Before the war, Schwarzschild, one of the ablest of German astronomers, found spectroscopically that the brighter stars in this cluster are all receding from the sun at the same rate, and noted that this rate is almost the same as in the case of the Hyades, while the proper motion of the group, though small, is directed nearly toward the point in the heavens toward which that group is moving. This suggested that the two clusters, though sixty degrees apart in the sky, were really moving in parallel lines in space, and that, in the course of millions of years, the inhabitants of the earth might see them drawing closer and closer to one another in the sky, shrinking in size and growing fainter as they went.

Knowing this point, it becomes possible to calculate the present distance of the Praesepe group. With the best data available, this comes out 560 light-years—four times the distance of the Hyades. A striking confirmation of this calculation has recently been furnished by another German, Kohlschütter. It has long been known that there is a remarkable relation between the brightness of the stars in the Hyades and their colors and spectral types. Stars in this cluster which are of the same real brightness as the sun are very similar to the sun in spectrum. Those fainter than the sun are redder, and more "advanced" in spectral type, while most of the brightest stars in the cluster are white, almost like Sirius in spectrum, and average almost forty times as bright as the sun. There are, however, four bright stars, clearly belonging to the Hyades, which are redder in color, and have spectra like Arcturus. These red "giants," which average some fifty times brighter than the sun, have their counterparts all over the sky, and have played a very important part in the theory of stellar evolution.

### Further Data on Distances

Kohlschütter has confirmed these facts regarding the Hyades, and made a similar study of the stars in Praesepe. In this case only the brighter stars of the cluster can be observed (the rest are too faint); but among these just the same situation is found. Most of the true members of the cluster are white, while a few, equal in average brightness to the others, are strongly reddish.

In each case the average apparent brightness of the stars is just about one-tenth of the apparent brightness of the corresponding stars in the Hyades. If we assume, as seems very probable, that the actual brightness of the stars of similar character is the same in the two clusters, we are led to a distance for Praesepe of 450 light-years—agreeing with the other as well as it is reasonable to expect, on account of the uncertainty of some of the data. The average of the two determinations, 500 light-years, is probably a very good approximation to the actual distance of Praesepe.

It may be added that the brighter stars in Coma Berenices show a similar distribution in color and spectrum, which indicates that the distance of the cluster is 300 or 400 light-years. The distance of the Pleiades, estimated in other ways, is probably about 300 light-years.

At 9½ o'clock: December 30.

**NIGHT SKY: DECEMBER AND JANUARY**

### The Heavens

Our map shows that three of the four clusters of which we spoke are now well observable. The Pleiades and Hyades are close to the meridian and very high in the sky. Practically all the stars near Aldebaran except Aldebaran itself belong to the latter group. Praesepe is well up in the east, below Castor and Pollux. The stars Gamma and Delta Cancri, which are close to it on each side, were called by the ancients the "Aselli," the donkeys which are browsing at the manger. Coma Berenices has not yet risen.

The southeastern sky is very fine, with Orion, Canis Major, Canis Minor and Gemini. With the splendid stars Sirius, Rigel, Betelguese, Procyon, Castor and Pollux in their number, and Aldebaran, Capella and Regulus among their close neighbors, it is with ample justification that these are often referred to as the "brilliant winter constellations." Leo and Hydra are rising, in the east, and Ursa Major is coming up in the northeast. Draco and Ursa Minor are low in the north, while Cassiopeia and Cepheus are well up in the northwest. Auriga and Perseus are overhead, and Andromeda and Pegasus conspicuous in the west. Cetus and Eridanus occupy the dull southwestern sky.

### The Planets

Mercury is a morning star, and is best seen about the time of his greatest elongation on the 3rd, when he rises about 5:30 A. M. Venus is an evening star, and sets about 7:30 P. M. in the middle of the month. Mars too is an evening star, and sets more than an hour after Venus when the month begins. Venus is moving eastward faster than he is, and by the end of the month the two planets are only about four degrees apart.

Jupiter is in quadrature, west of the sun, on the 10th, and crosses the meridian at 6 A. M. He is therefore visible all through the latter half of the night.

Saturn is about six degrees east of Jupiter, and also visible after midnight. Uranus is in Aquarius, and sets at about 10 P. M. in the middle of the month. Neptune is in Cancer, and is observable in the morning hours.

The moon is in her last quarter at 11 A. M. on the 2nd, new at 5 A. M. on the 10th, in her first quarter at 10 A. M. on the 18th, full at 8 A. M. on the 25th, and in her last quarter again during the last hour of the year. She is nearest us on the 25th, and farthest away on the 13th. During the month she passes near Jupiter and Saturn on the 3rd, Mercury of the 8th, Venus on the 14th, Mars on the 15th, Uranus on the 16th, Neptune on the 28th, and Jupiter and Saturn once again on the 30th.

At 10 P. M. on the 21st the sun reaches its greatest southern declination, and enters the "sign of Capricorn," when, in almanac language, "winter begins."

Destruction of main and super-structure decks, looking toward bow

Effect of a single bomb on main deck. Note that bombs were placed and not dropped

## Bombing the Old Battleship "Indiana"

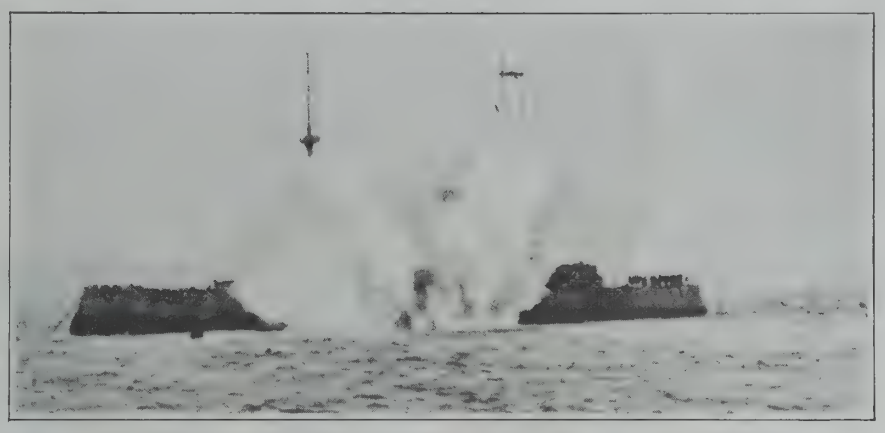
WITH a view to determining the effect which bombs of various sizes would have if dropped upon a battleship, that ancient craft, U.S.S. "Indiana" was selected as the subject of experiment. The "Indiana" class of three ships was laid down in 1891 and completed in 1895. The designs, therefore, of these ships are fully thirty years old, and consequently the "Indiana" has for many years been quite out of date, although she had a refit in 1905.

The vessel is 348 feet long, 69 feet, 4 inches broad, and displaces about 10,300 tons. She has a belt 15 to 18 inches in thickness, carries 17 inches of armor on the barbettes, and 8½ inches on the turrets. Her armament consists of four old 13-inch guns and eight 35-caliber 8-inch guns—at least that was the original armament. She is protected, in addition to the 18-inch belt, by a 3-inch protective deck at the water line and a 5-inch side protection from the water line belt up to the main deck. It should be understood that all of this armor is of the old Harvey type.

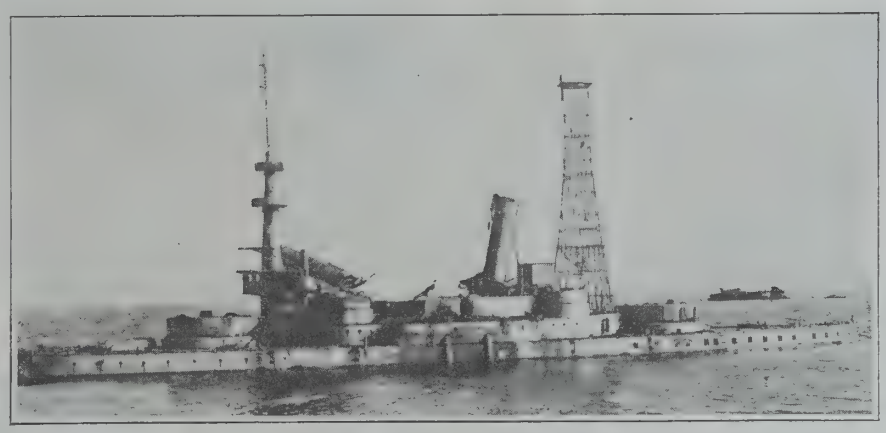
The "Indiana" is to be used by our modern fleet as a target, suffering the same fate as the old "Texas," renamed "San Marcos," the wreck of which can be seen in the offing beyond the quarter deck of the "Indiana" in one of our pictures.

Before subjecting her to gun fire, it was decided to anchor the "Indiana" in shoal water in Tangier Bay in the Chesapeake and cause her to settle upon the bottom by bombing the ship. It should be understood that the bombs were not dropped from airplanes, but were placed in positions, where their detonation would provide the information which the naval authorities were seeking as to bomb destructiveness on certain selected parts of the ship. The bombs were placed both within the ship and outside of it, some of the exterior bombs being in contact with the side of the ship below water and others being detonated at varying distances from the side. The results of this attack can be gathered from a study of the illustrations on this page.

These experiments were intended, not as a trial of bombing from the air, but merely to determine the effect of bombs of varying weight and power, if they struck at certain selected positions, or at varying distances from the ship. The art of bombarding from the air is yet quite in its infancy. To make a hit the plane must descend so low as to be fairly certain of being shot down. If it attacks out of anti-aircraft gun fire range, hitting the target becomes a matter of sheer good luck.



Detonation of bombs below water and near side of "Indiana"



The battleship "Indiana" on the mud where she will serve as a target. The wreck of the target "San Marcos" is seen beyond quarter deck of "Indiana"

**The effect of bombs on structure of "Indiana"**

## Battleship Guns on Submarines

IF anyone six years ago had stated that within a few years' time submarines would be going to sea carrying 12-inch guns, he would surely have been regarded as a visionary. The British Navy showed an astonishing freedom from conservative restraint in its handling of the naval problems which the war developed, and in two directions, that of the battleship and the submarine, we witnessed two remarkable developments, first, in the "Hood," a ship 860 feet in length, combining heavy battleship armor and armament with a speed of 32 knots, and here, in the "M-1," as it is called, in which we have a submarine carrying a gun that not so very many years ago was used only as the principal weapon on board of the most powerful battleships.

Just how far this latter development will go, it is difficult to predict. Lord Fisher, if we remember rightly, believes that the near future will see fleets of submersible battleships—big seaworthy vessels carrying full armaments of heavy guns and capable of entire submergence. It cannot be denied that "M-1" seems to point that way; but until she has been tried out under varying conditions and put to thorough tests of her habitability, seaworthiness, endurance, rapidity of submersion and all-round maneuvering ability, it would be rash to make any confident predictions as to the future of this type.

Although the British have been surprisingly frank in disclosing the particulars of the ships which they built during the war, it is significant that they have said very little about "M-1" and her sisters. In fact, the only definite statement that we have seen was one to the effect that these boats were built specially for service in the Dardanelles, where they were to be sent in for close bombardment of the forts.

The "M-1," a new type of British submarine, mounting a 12-inch gun

## State Friction and Lubricating Properties

IN an attempt to throw further light on an observation made by Rayleigh that, in certain cases, the friction is greater with a large amount than with a minute quantity of the same oil, experiments have been made on the static friction between perfectly clean glass surfaces and on the effect of a number of pure liquids when used as lubricants.

The clean surfaces were found to "seize," and when a sufficiently strong tangential force was applied to cause movement, the first effect was to tear the two glass surfaces. The liquids examined fall into two classes. The first class, the inactive fluids which have no lubricating effect, includes water, ethyl alcohol, ethyl ether, benzone, strong ammonia, and glycerine, but the last substance can exert the maximum lubricating effect if the surfaces are flooded.

Among active fluids were found sulfuric, hydrochloric, acetic, butyric, and oleic acids, a number of organic bases, castor oil, and paraffin. It was noticed in the case of some of the acids that the friction was slightly greater with the surfaces flooded than with an invisible film of liquid.

The evidence is against the conclusion that lubrication is a function of the quantity of lubricant when this is a pure chemical substance and when the viscosity is not very great, we are told.

How the home recorder is used and its mechanical details (diaphragm and cutting tool not shown)

## Home-made Records for the Disk-Type Phonograph

WITH the more or less complete disappearance of the cylinder-type phonograph, there passed away the former possibility of making one's own records—a feature that made for no end of added pleasure for the phonograph owner. The mechanical details of the usual disk phonograph are such as to preclude the making of phonograph records at home except through the use of some elaborate accessory.

It has remained for C. E. Sanders of New York City to develop a practical form of recording device which can be attached to any standard disk phonograph for producing home-made records. Aside from making records of various members of the family, the recorder can be employed for divers other purposes, such as in the school room, laboratory, singing school, and so on. At any rate, this device can be readily attached to any disk phonograph and used by anyone, because of its simplicity.

The starting point in our description of the home recorder is a special soft-wax disk, which is placed on the turntable in the same manner as the usual record. A metal disk, with a fine spiral groove, is placed over the center of the wax disk or blank. The reproducer is made in the form of a resonator and operates a fine cutting tool resting on the soft-wax blank. As the wax blank is turning, the recorder is slowly fed along through the small guide that rests in the spiral groove of the metal disk. Thus a good hill-and-dale cut record is produced, and by using the usual phonograph soundbox the music can be reproduced. Obviously, such a record, being made in soft wax, is not intended for long wear. If one desires to make it permanent, the manufacturers of the new device are prepared to duplicate it in the shellac compounds that we are accustomed to buying as regular records.

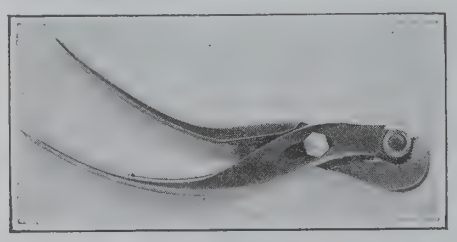
By means of a special fluid it is possible to efface the grooves and create a smooth surface for the next recording. Thus one blank can be used over one hundred times.

In the accompanying illustration will be noted the device attached to a standard disk phonograph, as well as a line drawing of the device itself. In this case the cutting tool and diaphragm are not shown; these members fit at the lower or smaller end of the horn.

A crank-operated shearing machine which expedites this kind of work

## An Interesting Plier Wrench

A WISCONSIN manufacturer has brought out a type of wrench which may be instantly adjusted to fit any size of pipe or nut within its capacity. The arrangement of the two sliding bearings and fulcrum give compound leverage and an exceedingly powerful grip may be obtained. The jaws of this wrench are always parallel. It is particularly adapted to tightening or removing nuts.



Any nut can be firmly held in the jaws of this pair of pliers

## Turning the Crank to Shear the Sheep

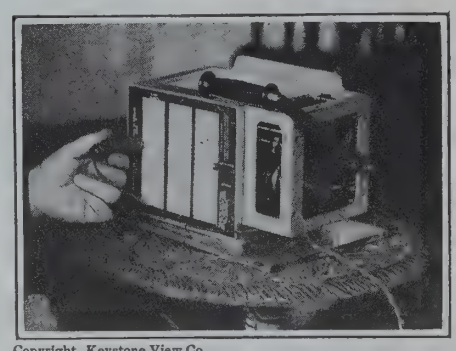
AN ingenious American has developed a hand-power shearing machine which makes short work of this particular task. As will be noted in the accompanying illustration, this device consists of a crank, reducing gears, transmission shafts with universal joints, and the shearing mechanism proper. Turning the crank causes the cutting blades to function. Two men are required with the crank-operated device, one for turning the crank and the other for the shearing.

## Truck With Electro-Magnetic Crane

A MOTOR truck company of Bay City, Michigan, has the distinction of manufacturing the first motor truck equipped with an electro-magnetic lifting crane. The machine has a 4-ton capacity and is a special order. It was tested recently and found to measure up to requirements. It is said that it will do the work of 20 laborers. A special crane was manufactured for this truck in which all operations are performed by power. It is equipped with quick-acting out-riggers in order to insure stability. The motor truck and crane can be used for loading or unloading cars of iron, etc., for handling scrap iron in yards, for loading other motor trucks or drays or for loading the motor truck itself, and can be used as a crane in handling any heavy object. This motor truck was manufactured as a special order for a Detroit concern, and will be sold at a consideration of $12,000.

## A Device That Takes the Place of the Radio Operator

RADIO equipment is absolutely necessary if an airman desires the maximum safety in flying. However, with the radio telephone handicapped by a very limited range, and the radio telegraph necessitating a knowledge of the telegraph code, the installation of a radio equipment aboard an airplane has heretofore presented numerous difficulties.



Copyright, Keystone View Co.

An automatic wireless transmitter which enables airmen to send messages

Now comes F. S. S. Wates of London, England, with an automatic radio transmitter which enables anyone to send certain wireless messages by merely manipulating a plug. The device, which is shown in the accompanying illustration, consists of clockwork driving a series of contact-making wheels, and a plug for making connections with any desired wheel. Each wheel has teeth which represent the dots and dashes of a given standard message, and the aviator plugs into the hole corresponding with the message he desires to transmit, and pulls the lever which operates the clockwork.

The automatic transmitter carries a large number of standard messages, a "forced landing" call, and the names of the leading towns along a given route. Thus if the airman is compelled to descend, he depresses a small lever and inserts the plug into the town nearest the forced landing. Obviously, this device, which weighs but ten pounds, is not a radio transmitter in itself; it must be employed in conjunction with a standard wireless set.

## Taking the Hard Work Out of Sawing

EVEN with the sharpest saw the task of sawing a hardwood board is anything but a sinecure. While our modern sawmills are models of efficiency and labor saving, the carpenter still does his work by tedious hand methods.

So it has remained for Charles M. Geiger of Chicago, Ill., to invent an electrically-operated hand-saw. His labor-saving device consists of a small electric motor which drives a small but extremely sharp saw through suitable means. The saw reciprocates at a high rate of speed, so that there is very little resistance offered to its motion by the wood being cut. In this manner, so we are told, the electric saw can be held in position with the right hand, while the left hand guides the reciprocating blade along.

The electric hand saw which speeds up sawing operations

## Something New in Tire Rims

DESPITE the many ways of putting an automobile tire on its rim, this field still appeals to inventors because the present ways are by no means the last word in convenience and dispatch. One of the latest ideas for tire rims is that shown in the accompanying illustration. Here is an automobile tire rim that can be taken off one shoe and transferred to another shoe in thirty seconds, according to its inventor. It is made in two parts, with two other pieces of the rim hinged together. The rim, when placed on the shoe, is locked with a small lever that works on a swivel at the bottom of the rim. The tire is placed on the rim and the two small sections of the rim are forced together as shown. The little clamp then holds the two sections in place.

A tire rim that can be transferred from one shoe to another in thirty seconds

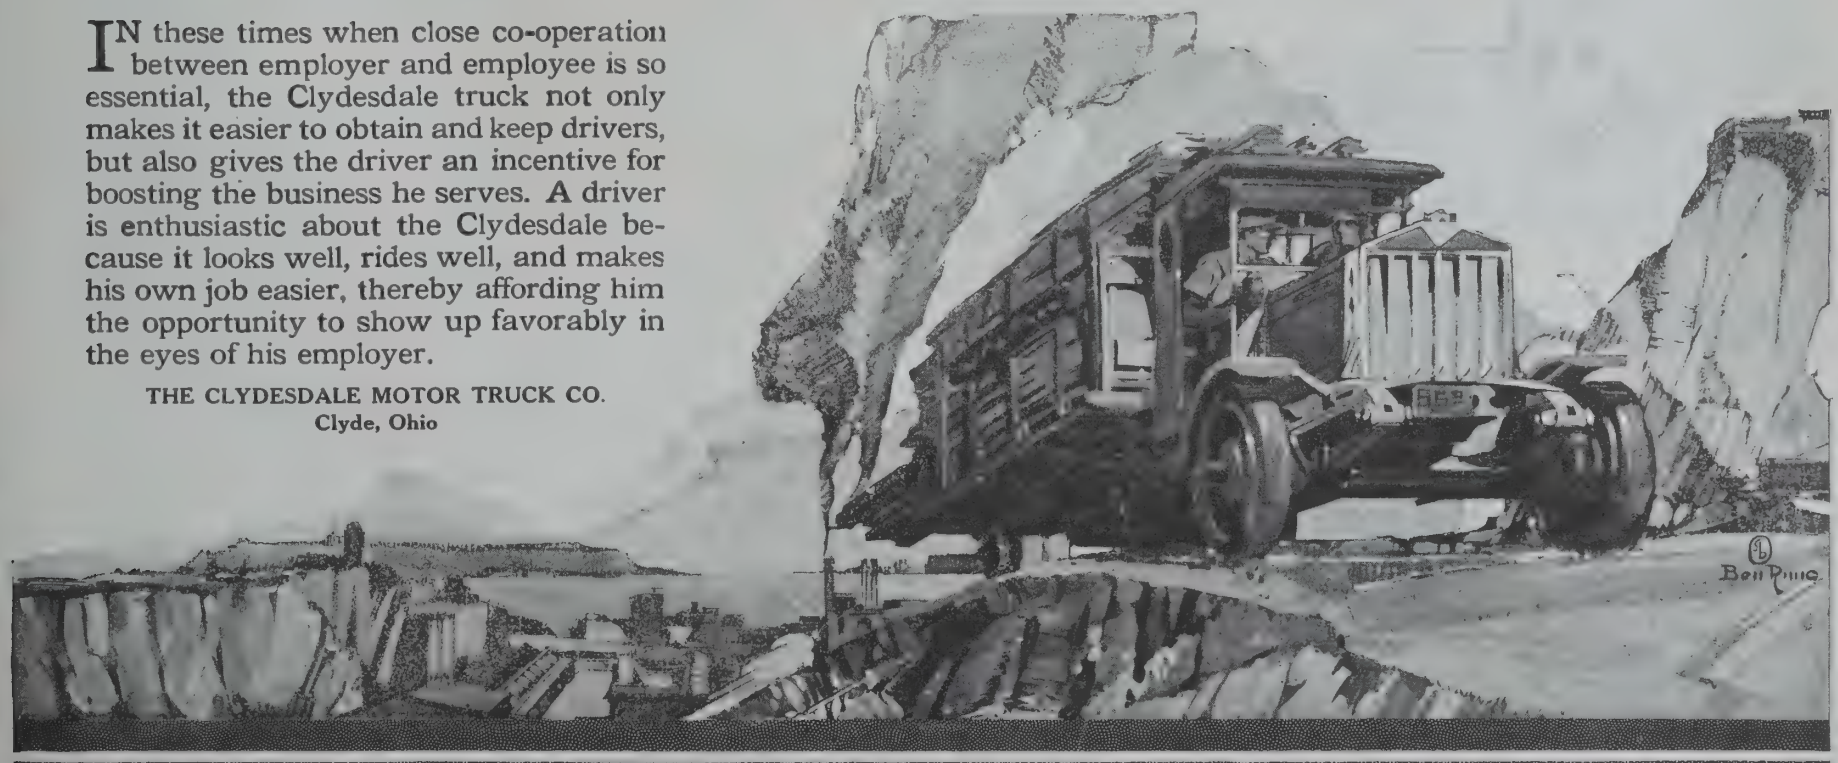
# PERFORMANCE

## WHY DRIVERS SWEAR BY THIS TRUCK, NOT AT IT

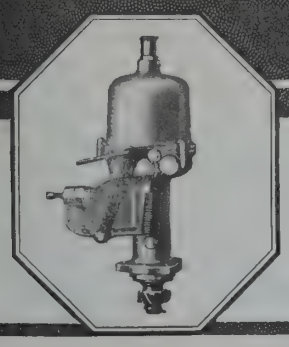
WHILE the purchase of the first truck may not be influenced by the driver's opinion, the performance of that truck in the hands of the driver often determines the selection of a second one. Clydesdale preference among drivers is founded upon two facts—mechanical excellence which includes power, adequate speed and ease of adjustment, together with the Clydesdale Controller which enables the driver to forget everything but the road.

IN these times when close co-operation between employer and employee is so essential, the Clydesdale truck not only makes it easier to obtain and keep drivers, but also gives the driver an incentive for boosting the business he serves. A driver is enthusiastic about the Clydesdale because it looks well, rides well, and makes his own job easier, thereby affording him the opportunity to show up favorably in the eyes of his employer.

THE CLYDESDALE MOTOR TRUCK CO.
Clyde, Ohio



# CLYDESDALE
## MOTOR TRUCKS



**"The Driver Under the Hood."** Just as the locomotive engineer looks to his fireman to see that enough steam is maintained to pull the load, the driver of a Clydesdale truck depends upon the Clydesdale Controller to keep the motor going at whatever speed is necessary to pull the load.

Whether up or down hill, through mud or sand, over rough or smooth roadbed, the Clydesdale will travel at a uniform speed once the throttle is set. On an upgrade, the controller feeds the motor more gas. On a down-grade, it cuts down the gas. All the driver needs to do is steer and shift gears when necessary.

# HARD RUBBER
## AN ESSENTIAL INDUSTRIAL RAW MATERIAL

HARD RUBBER—rubber hardened by a process of compounding and vulcanizing—is a tremendously important factor in the making of hundreds of mechanical devices, additional to its common and familiar use for fountain pens, dressing combs, smoking pipe bits, cutlery handles and automobile storage battery jars. For sixty-nine years the American Hard Rubber Co. has been making this material and its products. We are not only the largest exclusive hard rubber producers but the pioneers as well.

Our technical experts will advise with you, no matter how simple or how complex an article or a part for some article you need. Probably the important mechanical, chemical and electrical properties possessed by hard rubber will offer you the very opportunity wanted.

Let us tell you how and why you should employ the wonderful properties of hard rubber in your manufacturing problem. You incur no obligation by writing us.

**American Hard Rubber Company**
**11 Mercer St., New York**
Largest Manufacturers in the World of Hard Rubber and its Products

## SONNEBORN PRODUCTS

"We are very much pleased to say that we used Cemcoat through various sections of our Plants, applying it over woodwork, plaster and iron, and the result is highly satisfactory. In Cemcoat we have a coating which will not peel off, but will give satisfactory service. We take pleasure in recommending its use for factories where sanitation and maximum light are essential."—*Purity Oats Company.*

**Cemcoat**
THE PERFECT MILL WHITE

retains its glossy whiteness longer, because the ordinary yellowing and deteriorating gums and impurities are refined out of the Linseed oil which is then ground with the whitest pigments.

Cemcoat is elastic and durable because of the addition of imported gums.

It spreads easily, and because of its density, requires but two coats.

SONNEBORN PRODUCTS

**LAPIDOLITH** TRADE MARK
makes old or new concrete floors dust-free and wearproof by chemical action. Just flush it on.

**LIGNOPHOL** FOR WOODEN FLOORS
the modern wood preservative, gives new life to old or new wooden floors.

Get more light in your factory—free light reflected from glistening, mirror-like Cemcoated walls.

Cemcoat is furnished in Gloss, Flat, Eggshell, White and colors.

Write for testimonials, color card and literature.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

## Of General Interest

CAN COVER.—J. M. HATFIELD, 1111 N. Penn. Ave., Independence, Kan. This invention has for its object to provide a device especially adapted for enclosing cans of nitroglycerine and other explosives, wherein a relatively soft, flexible cushioning casing is provided for containing the can and for covering every part thereof to prevent the possibility of frictional contact of the can with other objects.

WINDOW CLEANER.—M. GOLDSTONE, 496 Chauncey St., Brooklyn, N. Y. The primary object of the invention is to provide a mechanically-driven window cleaner, which may be used to clean windows or other surfaces at a rapid rate without employing a ladder or for cleaning large show and store windows where considerable surface is exposed and considerable manual labor necessary.

REVOLVING HOUSE.—S. M. STEVENS, 1 Ravenscroft Rd., Asheville, N. C. This invention particularly relates to dwellings adapted for sick persons, or what are known as outdoor sleeping rooms; the object is to provide a dwelling having an open side which may be revolved in order to face in any desired direction. A further object is to provide electrically-operated driving means for revolving the house, the house being fitted with a number of conveniences.

WINDOW VENTILATOR.—F. SCELTZ, P. O. Box 380, Harrison, N. Y. The invention relates to a window ventilator which will permit a free movement on the part of the frame, a filtering element being incorporated with the structure insuring against the entry of impure air, the filter being readily cleanable at all times; the ventilator will also permit of an adjustment of the flow of air.

FILM HOLDER.—C. L. BAMBRIC, Brooks, Alberta, Canada. The object of the invention is to provide a film holder which will maintain a film in a stretched out condition without danger of creasing while allowing an easy washing thereof or dipping into the developing solution. Another object is to provide a holder which is readily adjusted for different widths of films.

MARKING DEVICE.—C. M. GRAVATT, Cold Springs, Okla. Among the objects of the invention is to provide a device which is especially adapted for marking cloth or clothing of any character so as to identify the material or article; it is especially adapted for use in connection with laundry work to distinguish the property of different customers.

TRUNK BAND.—R. T. EMERY, 121 Fellsway, W. Medford, Mass. The invention relates to trunk bands or straps preferably of bendable material which can be positioned around a trunk and securely locked in place, and when in such position will operate to strengthen the trunk and prevent injury as well as prevent opening of the trunk by unauthorized persons. A further object is to provide a device which will not disfigure the trunk.

PERPETUAL CALENDAR.—J. L. HUTSON, Shelbyville, Tenn. The object of the invention is to provide a perpetual calendar adapted to indicate any desired date of either the Julian or Gregorian system. Another object is to permit the user to rapidly set the calendar for any date of past, present or future years. Another object is to permit the user to set the calendar for the present month and to allow of making the desired changes at the end of a month or year for the next ensuing month of a year.

ROADWAY.—A. ANFINSON, Wakonda, So. Dak. The object of the invention is to provide mechanism for use in connection with ordinary country highways, for converting said highways at small expense and in a minimum of time into metaled road ways; to provide relatively narrow tracks of plastic material capable of hardening, such for instance as concrete.

EGG MIXER.—R. G. WILSON, Davis, W. Va. This invention relates generally to mixers, and more particularly to a portable hand mixer for domestic use in mixing fluids and semi-fluids, the object being the provision of a simple, inexpensive apparatus which may be readily cleansed after using and thus maintained in highly sanitary condition.

## Hardware and Tools

DOUBLE CLAMP.—G. T. BENTON, Willow Springs, Mo. The invention relates more particularly to a clamp which may be utilized for various purposes in connection with the fitting and setting of doors, windows and the like, the object being the provision of a simple, effective double clamp of the jointed nature which facilitate certain specific operations in addition to its general application.

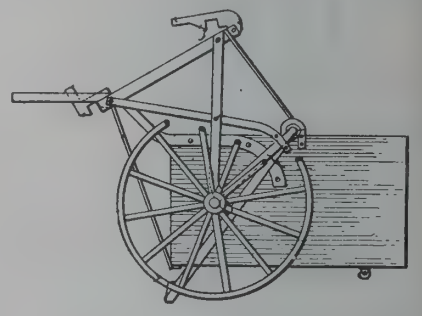
## Machines and Mechanical Devices

PULLEY.—A. SGRITTA, address A. Sgritta & Co., 94 Spencer St., Brooklyn, N. Y. The invention relates to belt-carrying pulleys for the transmission of power, and resides specifically in providing the rim of the pulley with a nurling to prevent the slipping of the belt and the lateral displacement and disengagement thereof, thus effecting a saving in power and economy of fuel, itme and labor..

PUMP.—H. M. HALL, Box 464, Wilcox, Arizona. The invention has for its object to provide a pump wherein the parts are so arranged that the barrel and plunger of the pump, together with the valves, may be easily and quickly detached from the suction pipe, or connected therewith without the necessity of pulling the said pipe from the top of the ground.

## Pertaining to Vehicles

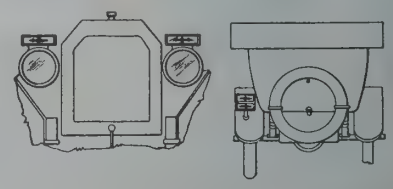
SELF-LOADING COAL AND GRAIN TRUCK.—J. A. KLOVSTAD, Hope, N. D. The invention has reference more particularly to that type of hand trucks that are designed to be self-loading and useful on farms, in cars, and warehouses, its main object being to provide a hand truck that will quickly load itself, and can be transported from place to place with and without its load.



A SIDE ELEVATION OF THE TRUCK IN POSITION FOR BEGINNING TO LOAD

RESILIENT WHEEL.—M. B. DISKIN, 76 W. 3rd St., New York, N. Y. The invention relates particularly to wheels having rigid rims and flexible spokes. Among the objects is to provide a wheel for vehicles which shall possess the desired resiliency for the comfort of the occupants of the vehicle and for practical purposes and yet shall not be subjected to the inconveniences incident to the use of pneumatic tires.

DIRECTION INDICATOR.—R. P. SAFELY, 410 42nd St., Oakland, Cal. The primary object of the invention is to provide an electric direction indicator for motor vehicles which can be conveniently manipulated by the driver or person sitting next to him to indicate to an approaching vehicle the direction that the vehicle is to take, for instance, when making a righ or left hand turn around corners. A further object is to so construct the device that it may be installed on a vehicle as an accessory.



A FRONT AND REAR VIEW OF MOTOR VEHICLE WITH INVENTION APPLIED

TRANSMISSION MECHANISM. — C. A. GROTZ, 4032 N. Francisco Ave., Chicago, Ill. An object of the invention is to provide a transmission mechanism by means of which any speed from zero to a maximum may be obtained by the manipulation of a single member such as a foot pedal or a lever. A further object is to provide transmission mechanism which may be used on all types of motor-driven vehicles, and which eliminates the bringing of gears into mesh and the consequent noise and wear occasioned thereby.

LEGAL NOTICES

**PATENTS**

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

## That Parallel Postulate

(*Continued from page 565*)

zation which the Euclidean has demanded that we produce, and the one which in the hands of the modern geometer has shown results.

In this two-dimensional geometry of surfaces in general, that of the plane is merely one special case. Certain of the features met in that case are general. If we agree that we know what we mean by distance, we find that on every surface there is a shortest distance between two points, together with a series of lines or curves along which such distances are taken. These lines or curves we call geodesics. On the plane the geodesic is the straight line. On surfaces in general the geodesic, whatever its particular and peculiar shape, plays the same rôle that is played by the straight line in the plane; it is the secondary element of the geometry, the surface itself and all other surfaces of its type are the tertiary elements. And it is a fact that we can take all the possible spheres, or all the possible French-horn surfaces, and conceive of space *as we know it* being broken down by analysis into these surfaces instead of into planes. The only reason we habitually decompose space into planes is because it comes natural to us to think that way. But there isn't a true, honest-to-goodness geometrical plane in existence any more than there is an honest-to-goodness spherical surface: so on intrinsic grounds one decomposition is as reasonable as another.

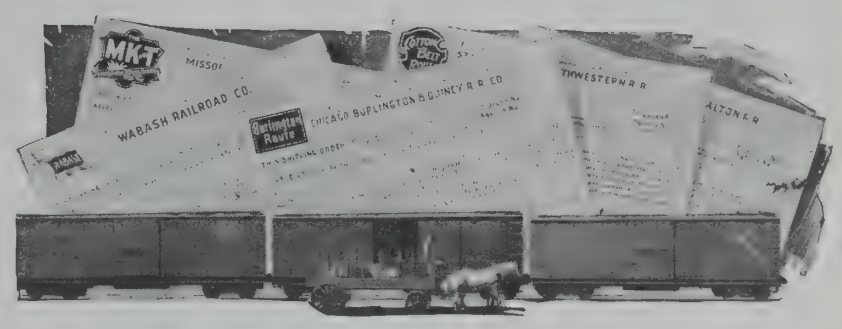
Certain of the most fundamental postulates are obeyed by *all* surfaces. As we attempt to discriminate between surfaces of different types, and get, for instance, a geometry that shall be valid for spheres and ellipsoids but not for conicoids in general, we must do so by bringing in additional postulates that embody the necessary restrictions. A characteristic shared by planes, spheres, and various other surfaces is that the geodesics can be freely slid along upon themselves and will coincide with themselves in all positions when thus slid; with a similar arrangement for the surface itself. But the plane stands almost unique among surfaces in that it does not force us to distinguish between its two sides; we can turn it over and still it will coincide with itself; and this property belongs also to the straight line. It does not belong to the sphere, or to the great circles which are the geodesics of spherical geometry; when we turn one of these over, through the three-dimensional space that surrounds it, we find that the curvature lies in the wrong way to make superposition possible. If we postulate that superposition be possible under such treatment, we throw out the sphere and spherical geometry; if we postulate that superposition be only by sliding the surface upon itself we admit that geometry—as Saccheri failed to see, as Lobatchewsky realized, and as Riemann showed at great length in rehabilitating the "obtuse-angled hypothesis." Lobatchewsky's acute-angled geometry is realized on a surface of the proper sort, which admits of unrestricted superposition; but it is not the sort of a surface that I care to discuss in an article of this scope.

### Where Euclidean Geometry Stands

Euclidean geometry is the natural and easy one, I suppose, because it makes it easy to stop with three dimensions. If we take a secondary element, a geodesic, which is "curved" in the Euclidean sense, we get a tertiary element, a surface, which is likewise curved. Then unless we are to make an altogether abrupt and unreasonable break, we shall find that just as the curved geodesic generated a curved surface, the curved surface must give rise to a "curved space"; and just as the curved geodesic needed a second dimension to curve into, and the curved surface a third, so the curved three-space requires a fourth. Once started on this sort of

# Your Transportation Problem

## —*The Answer*



THE successive increases in eastern freight rates since 1914 of 5%, 15%, 25% and 40%, and corresponding advances in express rates, have figuratively removed New York eastward into the Atlantic Ocean some 1,500 miles, as measured by the present carrying charges to the Middle West.

Slow rail service has doubled and tripled the time in transit, making long-haul distribution economically impossible and consequential interest charges excessive.

While the raw materials and markets of the Mississippi Valley, Middle West and Far West have been further removed from the long-haul eastern manufacturer, they have been drawn closer to the short-haul St. Louis manufacturer.

The relatively better transportation service enjoyed by St. Louis industries is a big factor in economical production and distribution. Nine-tenths of the railroad embargoes during and since the war, so costly to industry, were placed because of freight jams and blockades in the East, where there is one-third of the population of the country and only 17% of the railroad mileage.

The per capita inefficiency of industrial labor has been, and is, greatest in the congested eastern sections, and is in ratio with the decrease in efficiency of transportation.

## A Mid-West Factory in St. Louis

commands the advantages of short-haul and better service via 26 railroads at low relative charges to more than 60% of the country's buying power—and real choice between all export routes. Mississippi River service at 80% of rail rates.

The central location of St. Louis is as if "made to order" for present and prospective economic conditions.

The booklet "St. Louis as a Manufacturing Center" tells an interesting story. A letter will bring it, if addressed to

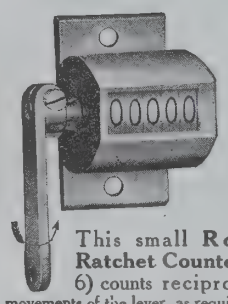
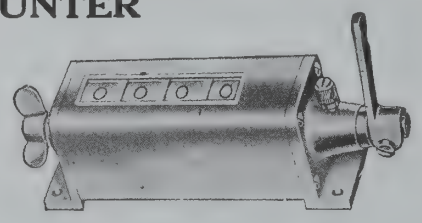
# Economize on Machine-Hours

More is made of the time put in at machines, when the worker sees the product of his time *recorded*. You get a production that really amounts to a wage-reduction, by the saving in *time* in getting a given run out of a machine with a

**Veeder COUNTER**



This small **Rotary Ratchet Counter** (No. 6) counts reciprocating movements of the lever, as required in recording the product of stamping presses. When the lever is moved through an angle of 40 to 60 degrees, the counter registers one. The further the lever is moved, the higher the number registered. A complete revolution registers ten. This counter is adaptable to no end of small machines, simply by regulating the throw of the lever. Price $2.00.
(Cut nearly full-size.)



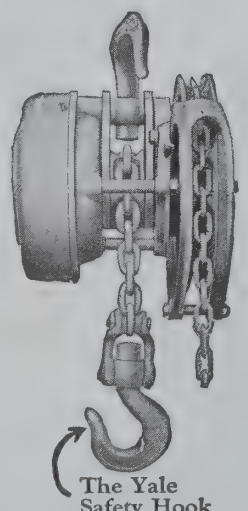
This large **Set-Back Rotary Ratchet Counter** records the output of punch presses, metal-stamping machines and others where a reciprocating movement indicates an operation. Registers one for each throw of the lever, and sets back to zero from any figure by turning knob once round. Provided with from four to ten figure-wheels, as required. Price with four figures, as illustrated, $11.50. (List.) Equipped with lock and keys to prevent tampering with the record, $2.00 extra.
(Cut less than half-size.)

*The Veeder booklet shows counters for every machine where they're profitable to the user. Send for copy and see what it offers for your purpose.*

The Veeder Mfg. Co., 18 Sargeant St. Hartford, Conn.

TRADE YALE MARK

YALE MADE IS YALE MARKED



The Yale Safety Hook

## The Safety Hook

EVERY Yale Chain Block has a Yale Safety Hook, so made that it gives visible warning if seriously overloaded.

The special metal used in drop-forging these hooks prevents their breaking. Instead, if an unsafe load is lifted, the Yale Safety Hook *shows* the operator by slowly opening.

This unusual feature is but one of the many which make Yale Blocks so well known for safety and economy.

The Yale & Towne Mfg. Co.
*Makers of the Yale Locks*
Stamford Conn.

SPUR-GEARED BLOCK

thing, there doesn't really seem to be any end.

Nevertheless, we must face the possibility that the space we live in, or any other manifold of any sort whatever with which we deal on geometric principles, may turn out to be non-Euclidean. How shall we finally determine this? By measures—the Euclidean measures the angles of an actual triangle and finds the sum to be exactly 180 degrees; or he draws parallel lines of indefinite extent and finds them to be everywhere equally distant; and from these data he concludes that our space is really Euclidean. But he is not necessarily right.

We ask him to level off a plot of ground by means of a plumb line. Since the line always points to the earth's center, the "level" plot is actually a very small piece of a spherical surface. Any test conducted on this plot will exhibit the numerical characteristics of the Euclidean geometry; yet we know the geometry of this surface is Riemannian. The angle-sum is really greater than 180 degrees; lines that are everywhere equidistant are not both geodesics.

The trouble, of course, is that on this plot we deal with so minute a fraction of the whole sphere that we cannot make measurements sufficiently refined to detect the departure from Euclidean standards. So it is altogether sensible for us to ask: "Is the universe of space about us really Euclidean in whatever of realized geometry it presents to us? Or is it really non-Euclidean, but so vast in size that we have never yet been able to extend our measures to a sufficiently large portion of it to make the difference from the Euclidean standard discernible to us?"

This discussion is necessarily fragmentary, leaving out much that the writer would prefer to include. But it is hoped that it will nevertheless make it clear that when the contestants in the Einstein competition speak of a non-Euclidean universe as apparently having been revealed by Einstein, they mean simply that to Einstein has occurred a happy expedient for testing Euclideanism on a smaller scale than has heretofore been supposed possible. He has devised a new and ingenious sort of measure which, if his results be valid, enables us to operate in a smaller region while yet anticipating that any non-Euclidean characteristics of the manifold with which we deal will rise above the threshold of measurement. This does not mean that Euclidean lines and planes, as we picture them in our mind, are no longer non-Euclidean, but merely that these concepts do not quite so closely correspond with the external reality as we had supposed.

### Illiterate Adults

(*Continued from page 566*)

were ignorant of the American language. During the war we have had an additional immigration of a million more adults who cannot speak our language. At present the rate of immigration is larger than during the tidal wave years of 1913 and 1914. The Literacy Test does not exclude illiterates, it merely eliminates some few, for the law makes many exceptions and no ability to read in our language is required. All that is required is knowledge of the simplest words in any foreign language.

The majority of immigrants now find so many of their compatriots here that the incentive to learn American grows less each year. As a rule employment is obtained readily at good wages by the alien without any knowledge of our language, with the consequence that we are rapidly becoming a polyglot nation, and mutual understanding through the existence of a common language is more and more difficult. This leads to increased overhead charges of all sorts in industry, makes a truly representative form of government difficult to attain, prevents industrial cooperation, lowers standards of living, im-

Weber Crank-Pin Re-Turning Tool

**No Filing**
**No Offsetting**
**No Jigs**

This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

KEYSTONE COPPER STEEL
AMERICAN SHEET AND TIN PLATE COMPANY, Pittsburgh, Pa.

pairs the health and wellbeing of every community, and even threatens our very form of government.

Heretofore we have prided ourselves upon our literacy. We have taken it for granted that every American could read and write. But the result of the draft showed us that nearly a third of the picked manhood of the nation were unschooled to the point where they could not be accepted as soldiers because they could not understand military instructions of the most elementary sort. Scores of thousands could not distinguish between right hand and left hand. Those who could not read a word included native-born whites and negroes as well as foreign-born.

Slight provision is made in our schools for the needs of the adult. In our public schools, moreover, due to scanty pay, there is a present lack of sixty thousand teachers. This is the condition facing the administrators of education for children under sixteen or eighteen. The additional problem of teaching the adult foreign-born illiterate, the unschooled mountain white, and the negro is so vast that though every one of our seven hundred and fifty thousand public school teachers were to relinquish their work with children and should devote themselves to the instruction of adults who cannot read and write, even then we should not have a force of teachers sufficient to cope with the situation.

Illiteracy therefore is manifestly not the sole business of the schools and the school authorities. It concerns every American. It affects especially the employer, whether in industry or in the household. Half of the illiterates are women, many of whom are employed in factories or in homes.

Evening schools reach only a few of the most ambitious, for the majority of those who cannot read or write or speak our language cannot go to school. Evening schools in New York City have succeeded in the course of a year in reaching scarcely one-half of one per cent of the hundreds of thousands of illiterate aliens. The reasons are many: Industrial fatigue, family obligations, lack of means, and especially faulty school methods and failure to arouse and maintain interest.

A practical and effective method of teaching the illiterate to read is the institution of public school classes in the places of employment. The first workers' class was instituted in 1913 in New York City. There are now more than a thousand such classes in industrial establishments everywhere. In Chicago alone there are several hundred such classes in successful operation. It is not practicable to carry on these classes with complete success unless provision is made for attendance without loss of pay during daylight hours. An hour a day five days a week should be given during the period of instruction.

The latest developments in methods of instruction are Self Help Lessons in American to be put into the hands of the learner himself, and so arranged in method and manner as to be interesting and capable of being used without the aid necessarily of a trained instructor. Such elementary graded progressive lessons provide a language machinery which an adult can use successfully with slight help perhaps from a child who goes to American public school or from some friend who has had a little schooling. Such lessons can eventually be put in the hands of everyone.

It is practicable to develop a One Language Nation as well as a literate nation, but this needs the informed and hearty teamwork of directors of industry, leaders of labor, school authorities, legislators, the press, and the general public.

Democracy is measured by ability of each to share in the thought of all. Today thought is shared by means of the printed word. Therefore inability to read and absence of the reading habit is a barrier to true representation, be it social, industrial, or political. Yet we persistently avoid this obvious fact in our consideration of industrial relations and methods of civil government. The problem of the elimination of illiteracy from the United States is the problem of the most vital importance to us all, for it is basic to national prosperity and is the only means of unifying the nation.

## Motor Trucks in Orchards

(*Continued from page 567*)

be used for different classes of work. In hauling fruit trays, or baskets, for instance, it is found desirable to have a wide platform on the chassis, while for other uses a closed or box body is required. In the raisin district of Fresno County motor trucks are used in large numbers to haul the grapes for drying and again from the drying fields to the packing houses and store rooms. The same is true of the prune districts of the Santa Clara Valley, while in the cherry center, in Alameda County, the trucks are largely used to haul the fresh fruit to market or to the cannery. Lake County is famous for its pears, and here, too, the motor truck is playing an important part in solving the transportation problems of the growers. In the orange and lemon districts of southern California, and the olive district of Butte County, motor trucks are depended upon to move the fruit from the orchards to the packing sheds.

As an example of the adaptability of the motor truck to different kinds of hauling jobs, we have the experience of Mr. Charles W. Mann, a fruit grower of Methuen, Mass. Mr. Mann has four different bodies for his 1½-ton truck, and since its purchase in 1911 this truck has run over 100,000 miles. He uses it to collect thousands of barrels of apples from orchards within a radius of 10 to 15 miles and then to deliver them to nearby markets, to freight cars, or to Boston, 11 miles distant. In one season this truck made two round trips to Boston daily for four weeks, averaging 120 miles a day.

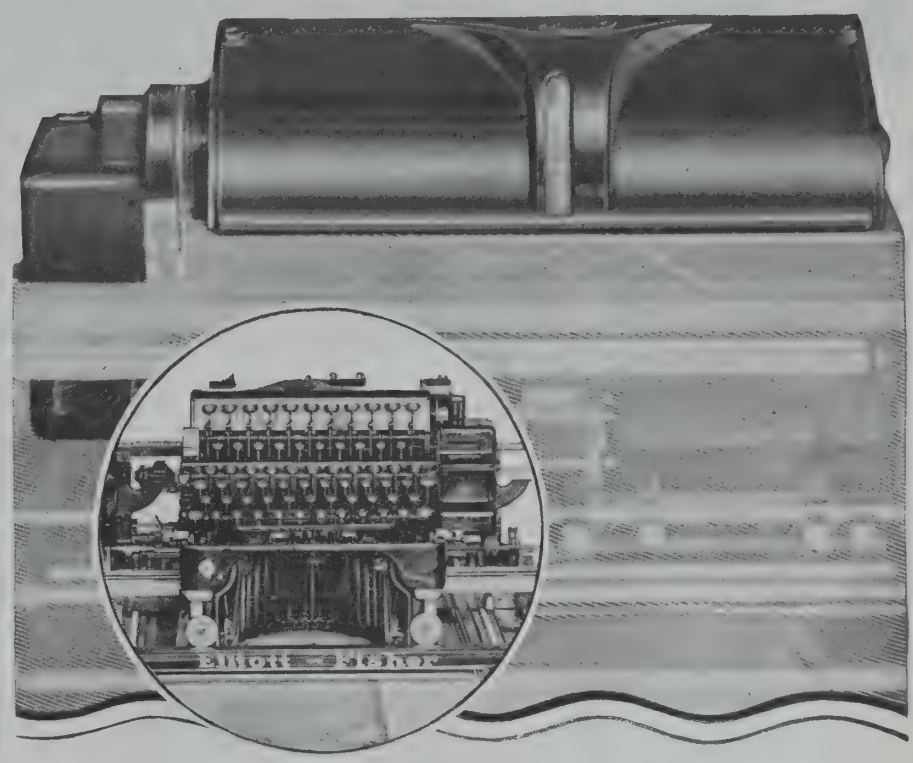
With a double-deck body, Mr. Mann's truck will carry 50 bushels of strawberries or tomatoes without bruising them, and in one season he sold from it 50,000 baskets of berries and 4,000 bushels of tomatoes. The truck also hauled over 150 tons of hay in one season.

That motor trucks will reduce transportation costs has been shown in the experience of many owners. Mr. H. B. Wayland operates an orchard near Heards, Va., and the roads in his vicinity are not particularly good and some of them have high grades. In the old days Mr. Wayland used several four-mule teams for hauling to and from his orchard, and he estimated the daily cost of each of these teams at $5.22 even when idle. He hesitated about purchasing a truck on account of the condition of the roads, sometimes very muddy, but he finally purchased a 3-ton motor truck and in five months this truck covered 2,160 miles before winter closed the roads. The cost figures, in spite of the fact that this five months' work was of the roughest type, including regular road freighting and logging over narrow mountain trails on short, hard hauls, showed a net saving of 10 cents per ton-mile over mule and wagon haulage, and after this experience the mule teams were sold and the entire hauling work of the orchard done with the truck.

In the cranberry marshes of New Jersey the motor truck is doing good service, and in spite of the slippery bogs and the wide stretches of sands, the truck is supplanting animal teams. One such truck made from 20 to 25 complete 4½-mile trips daily during the picking season. The truck has replaced five teams and surpassed the record of the teams by approximately 100 per cent.

In many cases the use of motor trucks has enabled fruit growers to save their

REDMANOL
REG. U.S. PAT. OFF.
For Perfect Molding



Elliott-Fisher and many others

THE CLOSE-UP shows how Elliott-Fisher use REDMANOL in their nationally known bookkeeping machines. REDMANOL, for many others, is obviating the necessity for die-casting, stamping, shaping, and finishing. Its many admirable qualities (in addition to those briefly given below) make it ideal for a limitless variety of uses in any makers' products. Frequently it markedly cuts down production time while lowering production costs. Alway it is good-looking and exceedingly durable Very likely you could with advantage use this perfect molding compound in your product. Just ask us. We will tell you specifically what REDMANOL will do for you.

*Redmanol is also supplied in laminated sheets, rods and tubes*

We Help Manufacturers

**Our laboratories are constantly engaged in working out new applications for forward-looking manufacturers. It implies no obligation to submit your problem for solution. *Address Department 87.***

**Redmanol Chemical Products Co.**
636 W. 22nd St. Chicago, U. S. A.

Redmanol Qualities

- Resistence to extreme heat.
- Exceptionally high dielectric strength.
- Great mechanical strength.
- Excellent acid resistence.
- Unusual accuracy of dimensions.
- Singular beauty of finish.

*Now Ready! A New Book on a New Subject*
BEHIND THE MOTION-PICTURE SCREEN
*By Austin C. Lescarboura*

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.
Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Send for four page circular giving sample page and full table of contents.
*Size 6¼ x 9½, $3.50: postage—15c in the East, 20c to Chicago, 30c to the coast*
*One of the Most Attractive Books Ever Issued*

## Cover Crops for Our Orchards

(*Continued from page 567*)

husbandman for the renewal of the corn crop next year.

Not so with the fruit tree. It must serve long years; bear patiently all the vicissitudes of vegetable life; produce fruit abundantly, even in the extremity of old age.

Nor is the fruit tree indifferent to man's care and attention. It smiles its gratitude in terms of vigorous wood growth, luxuriant leafage, a profusion of beautiful spring bloom, and finally a crop of fruit richly tinted and colored to please the eye, and gushing with pleasant juices, wherewith to gratify the appetite of man.

Cover crops may be used handily and effectively in the art of mulching. Mown cover growths gathered about a tree, carefully placed in regular form, and to a proper depth, may be made to serve various purposes—stifle weeds or foul growths that may have sprung up around the tree, conserve moisture by preventing too rapid evaporation; and the refertilization of the soil immediately around the tree, where it is most needed.

Rainfall may thus be absorbed and held in suspension for the better nourishment of the tree; moisture from lower sources may be also brought up and made to do good service. And, as in a hundred other instances the farm tractor comes upon the scene as a most efficient tool to be used in the cultivation of cover crops.

It is both handy to use, and effective in its action. One of the most awkward phases of orchard culture that has come under my own observation was the cultivation of orchards by means of horsepower. Time and again I have watched some unlucky wight tooling a plow, a walking plow at that, and a pair of farm horses beneath the umbrageous roofage of a California orchard. The plowman, grasping tenaciously the two plow handles, plodding mile after mile in a muddy, sticky furrow; now watching the plow and then throwing a quick glance to his team, the occasional jerk on the lines which are hooked over his own neck because his two hands are otherwise engaged, and then emitting a blue streak of profanity for the better guidance of his team and the delectation of chance passersby, was the scene in outline.

A dull and sordid task calculated to exhaust the body and jar the moral fiber with bitter memories. Then the vain attempts to induce those poor horses, as the slow furrowing proceeded, reverently to bow their heads and crawl beneath the tree tops in order that the plowing might be carried nearer the vital parts of the trees!

But why recall those scenes of rustic toil and tribulation of the spirit, when they have passed, or are about to pass into the realms of oblivion and utter extinction?

And now we behold this emancipated son of toil seated cheerfully upon the throne of the farm tractor, gently steering the apparatus between innumerable rows of fruit trees, turning up the mellow mold through which he once plodded with leaden feet and heavy heart. Gently he guides the machine up beneath the low-bending branches until he seems to be in imminent danger of barking the tree.

But no: Never a bark! Neither is the tractor asked to bow its head; because it is headless and has an orchard top to it.

Now as to various plants that are adapted to cover crops under California orchard conditions: There is *Melilatus*, or Bitter clover. This is an early starter, makes a good growth during the winter, sometimes attaining the goodly

## "All Right, Then—I'll Go To Hell!"

"It was awful thoughts and awful words, but they were said and I let them stay said."

It had felt good to be all washed clean of sin and to be able to pray—but Huck couldn't tell Old Jim no matter how sure it would make him of going to Heaven.

So he tore up the note and swore he would never reform again. He would steal Jim out of slavery, he would—and if he could think up anything worse, he'd do that too. As long as he was going to hell anyway, he might as well make it worth while. Who ever knew the heart of a boy as does

# MARK TWAIN

### *12 Vols. At a Low Price*

## FREE—Rex Beach

### *5 Volumes*

Rex Beach is the most popular writer of thrilling stories living today. He is the man who knows, as no other, the big outdoors, that is the Klondike.

Plenty of humor—plenty of scrapping—big, raw-boned men who can whip their weight in wildcats—the women these men fight for and die for—all these you will find in Rex Beach's vivid, human novels.

## Only a Few Sets FREE

Rex Beach now costs you $2.00 for each volume in the book store. But we have made a small special edition and so as long as this small special edition lasts you can have 5 volumes—about $10 worth of books—**absolutely free.**

Rex Beach has sacrificed much of his royalty so that we can do this on one edition.

If you are prompt you can get your set free. If you are too late we will return the coupon—but don't wait.

Send the coupon for both sets for examination. Send no money—just the coupon. Send it at once.

**HARPER & BROTHERS**
*Est. 1817* **New York**

**HARPER & BROTHERS, 21 Franklin Square, NEW YORK**

Send me, all charges prepaid a set of Mark Twain in 12 volumes, illustrated, bound in handsome green cloth, stamped in gold, and Rex Beach in 5 volumes, bound in red cloth, free. If not satisfied, I will return them at your expense, otherwise I will send you $1.50 within 5 days and $2.00 a month for 14 months.

Name .....

Address .....

Occupation ..... Sc. Amer. 12-4-20

height of three feet before it is ready to plow under. It is not good either for hay nor forage but makes an ideal special green manure, or cover crop. Sow from ten to fifteen pounds of seed to the acre, and plant very shallow, say a quarter or a half inch deep.

Burr Clover, or *Medicago denticulata*, is a native of California; makes not only a good cover crop but a fine dry forage for summer use. In practical use the Latin name may be abandoned without endangering the crop.

Spring Vetch, or *Vicia sativa*, is a hardy plant and is extensively used as a cover crop. The seeds are of a large size, and it requires from sixty to seventy pounds to the acre for a proper seeding.

Hairy Vetch, or *Nicia nillosa* is a hardy winter plant; stands cold weather well and makes a luxuriant growth. Sow from 30 to 40 pounds of seed to the acre.

Canada field peas make both an ideal cover crop and a good forage plant for cattle. You may plant it late in the season, yet get a good crop. Sow from 70 to 80 pounds to the acre.

Sweet Clover, or Bokhara, or *Mililotus alba* makes a good cover crop. It is a biennial and is noted for its deep-rooting faculty. Sow ten pounds of seed to the acre.

### Asbestos in Architecture

(*Continued from page 572*)

water does not give the desired results, because the asbestos aggregate and the cement particles are drawn together in more or less separate groups or masses. Without going into details, these formations react in such a way to the water that they exclude all but a small percentage of that fluid; and as a consequence the imperfectly wetted mixture represents very largely nothing more than unhydrated cement bound together by a network of more thoroughly hydrated cement "gels." This fact explains why some asbestos shingles, corrugated roofing, and siding have failed to meet expectation.

In the Hatschek process, as standardized here by the best of our manufacturers, the order of procedure is as follows: First, 85 per cent of hydraulic cement of a superior grade and 15 per cent of asbestos fiber of the chrysotile variety are carefully mixed with water by means of a beating machine much like that employed in the production of paper pulp. Prolonged mixing and agitation make a uniform fluid composition having the properties of a colloidal diffusion. The small, solid particles will remain in suspension for a long while. The soft, pastelike mass lends itself readily to working on a millboard machine without setting or hardening the while. It seems that there is no separation of the cement even when the pulp is finally subjected to high pressure. At that time only clear water passes off the rolls.

After leaving the beating machine the colloidal substance goes to a vat where it is kept agitated until picked up by a fine wire screen mounted on a rotating cylinder. From this it is transferred to an endless belt of felt which brings the material between two horizontal steel rolls 96 inches in circumference and 42 inches long, where pressure is applied to expel much of the water. Despite the fact that the surface of the upper cylinder is highly polished, still it attracts the composition away from the felt belt and builds up upon itself successive layers of the substance until the desired thickness is attained. Next, the accumulation is freed from the cylinder by a single longitudinal cut which forms it into a sheet.

Owing to the numerous layers composing a sheet, the manner in which the asbestos fibers are interlocked as the succeeding layers are brought together under pressure and the completeness of the original mixing of the cement and asbestos, a final texture results possessing marked homogeneity and pronounced toughness. But don't let us anticipate.

# Clean ice-boxes

No housekeeper takes better care of her house or her refrigerator than we take of our refrigerator cars.

You are so used to having your meat come to you clean, fresh, and wholesome that you take it as a matter of course. But every refrigerator car that you see go rolling by represents scientific, painstaking care in preparation for its journey.

Every time a car is returned it is washed out thoroughly with scalding water.

When the car is thoroughly cleaned we put 2 or 3 tons of ice and 500 to 750 pounds of salt in the ice bunkers. The salt forces the melting of the ice, which in turn cools the cars.

By the time the car is ready to receive its load, this first ice has largely melted and 2 or 3 tons more of ice and salt have to be put in to keep the car and its contents cool.

The meat is then loaded into the car, great care being taken to see that the quarters of beef and cases of other products are properly spaced to insure a free circulation of cold air. Each 24 hours thereafter more ice and salt have to be put in at icing stations along the way. There must be no failure to keep the ice-boxes filled.

Swift & Company's inspectors keep close check of the cars as they move toward their destination, to see that each one is properly iced. Only through such scrupulous care and attention will meat arrive as it leaves our plants, clean, fresh, and wholesome, unaffected by seasons, weather, dust or contamination.

This is only a part of what Swift & Company has to do in its task of transforming animals into meat products and putting the products in the hands of retail dealers close to your residence.

The importance and magnitude of this work is out of all proportion to the minute recompense which Swift & Company gets, the profits from all sources averaging only a fraction of a cent per pound—less than a nickel a week to the average family.

## Swift & Company, U. S. A.

*Founded 1868*

**GILBERT P. FARRAR**

***Direct Advertising***

**220 W. 42nd St., New York**

After the sheets leave the rolls they are cut up into shingles and "starter pieces" in a way that results in comparatively little waste. These shaped units are then put between steel plates, and when a number of "sandwiches" are ready they are subjected to a pressure of 10,000 pounds to the square inch. This pressure removes the bulk of the moisture and gives the shingles and starter pieces a smooth surface. They are then seasoned, trimmed, drilled, bundled and stored for shipment. The residual moisture does not escape until it has indissolubly bound the cement and asbestos. As the moisture evaporates the shingle becomes more compact and tougher. In short, it grows stronger as time goes on.

In making corrugated roofing and siding the sheets from the rolls are placed immediately between corrugated metal plates and are subjected to a pressure of 20 tons or more to the square foot. This compacting pressure eliminates the minute voids that might otherwise remain in the material. The ultimate product is water resisting. After compression, the material is stored in a damp room to prevent drying out of the surface until the stuff is thoroughly set. Then follows a seasoning period. In manufacturing asbestos building lumber, which is turned out in the form of flat sheets of varying thicknesses, they are naturally placed in the hydraulic presses between flat plates. The lumber, when ready for marketing, can be easily sawed, cut, drilled, punched, and nailed in position. It is employed for walls, ceilings, paneling, and wainscoting. It is also used for doors, screens, pipe and wire conduits, table tops, fire walls, and the lining of elevator shafts, stairways, corridors, etc. Apart from the fact that the material is well-nigh indestructible and non-combustible, it has money-saving virtues, for it can be put in place much quicker than stucco or plaster, does not crack when exposed to the weather, and avoids the expense and labor of occasional painting.

With coal costing more from year to year, the heating of the home and other sheltering structures has become a matter of concern, and it is important to check radiation from the pipes and flues of steam, hot water, and hot-air conduits. This, asbestos coatings are doing but not to the extent that proper economy warrants. Similarly, cold water pipes which might sweat hurtfully in the presence of warmer air can have this tendency arrested by covering them with asbestos; and a protecting shield of this sort upon the water-supply pipes is one of the surest safeguards against freezing and a vexatious bill from the plumber. Again, asbestos jackets, lagging and the like can hold heat at bay in all kinds of refrigerating equipments—reducing outlays for either ice or initial energy, according to the system. Finally, asbestos building felt is an admirable substitute for the inflammable felts or papers now so commonly used as a floor lining and a general sealing medium in frame houses. Owing to its character as a non-conductor, this insulating felt serves also to arrest the penetration of heat in the summer months, thus making for a cooler habitation.

While the United States is the greatest user of asbestos products, our own mines yield less than 1 per cent of the raw material worked up here. It is said that Canada furnishes the world with 90 per cent of the marketable asbestos, and we use 60 per cent of the output of the famous Quebec mines.

## NEW BOOKS, ETC.

ELECTRO-DEPOSITION OF METALS. By Dr. George Langbein. Translated by William T. Brannt. New York: Henry Carey Baird and Company, 1920. 8vo.; 863 pp.; 185 engravings.

The entrance of this standard work upon an eighth edition has provided opportunity for a complete revision and a substantial enlargement. It contains encyclopedic information on electroplating, galvanizing, and electrotyping, the contact and immersion processes, coloring of metals, lacquering, and grinding and polishing. Shop equipment receives much attention, and not the least valuable feature of the work is the practical formulas and trade secrets that cover the solutions employed. Descriptions of machinery and apparatus are freely augmented by good illustrations, and the whole presentment is so plainly worded as to be immediately understandable to the plater and metal finisher.

ARTIFICIAL LIGHT. Its Influence Upon Civilization. By M. Luckiesh. New York: The Century Company, 1920. 8vo.; 366 pp.; illustrated.

It is hard for us to realize into what Egyptian darkness sundown plunged our world not so many years ago. The torch, the candle, the oil lamp, gas, electricity—this historical progress is entertainingly chronicled by the author. He tells of street lighting, home illumination, and artificial light in warfare and in spectacular effects. As usual, he has a word to say on lighting as a fine art; and he discusses light in its relations to health and safety, with some consideration of costs, and a chapter on the light of the future. This story of man's conquest of darkness is stamped with the ease of accurate knowledge and the ability to interest the general reader.

THE LIFE AND WORK OF SIR HIRAM MAXIM. By P. Fleury Mottelay. New York: John Lane Company, 1920. 8vo.; 230 pp.; illustrated.

The author was secretary to Sir Hiram, who furnished, by personal dictation and by manuscript accounts, much of the information that makes up the volume. Each section deals with a particular phase of inventive activity—the automatic gun, explosives, aerial navigation, gas machines, oil experiments, etc. Lord Moulton's introduction draws a picture of the man and inventor as he knew him, and an excellent frontispiece portrait shows Sir Hiram at the age of seventy-four. Appendices contain valuable notes and cite the list of patents granted the subject of the biography by the American and British Governments.

AMERICA'S MARITIME PROGRESS. By George Weiss and J. W. Leonard. New York: The New York Marine News Company, 1920. 4to.; 525 pp.; illustrated.

Large pages, tinted paper, good print-work and fine plates make very attractive this history of our wonderful rehabilitation. It recounts how American shipping pulled out of the plight in which it stood before the war, and shows how coöperation and standardization led to the breaking of building records and a forward leap in foreign commerce. Four-fifths of the work is devoted to descriptive sketches of representative companies of the shipping world, with biographies and photographs of the big men of the industry. Among the full-page plates are shipyard scenes, launchings and various types of our great cargo carriers.

AERONAUTICS. Fourth Annual Report of the National Advisory Committee for Aeronautics, 1918. Washington: Government Printing Office, 1920. 4to.; 654 pp.; illustrated.

The report gives a clear account of facts collected and verified and work done. The methods and machinery of important experiments are closely described, and there is a lay-out of general problems and activities with the trend of progress indicated. The technical papers, occupying the major portion of the large volume, include Nos. 24-50, and deal with nomenclature, navigational theory and phenomena, air propellers, general construction, tests of balloon fabrics, gas, and engine fuels, and other experiments and deductions. All interested in aircraft should follow recent development as here authoritatively outlined, and learn what our coöperating experts accomplished.

OCEAN SHIPPING. Elements of Practical Steamship Operation. By Robert Edwards Annin. New York: The Century Company, 1920. 8vo.; 427 pp.; illustrated.

"The Century Foreign Trade Series" makes its appearance with "Ocean Shipping," by a member of a great shipping firm. The sudden expansion of our fleet finds us hard pressed for men familiar with the machinery of foreign trade and the management and operation of its freighters. Here the ambitious man is given the gist of thirty years' experience—actual practice as it touches office organization, traffic management, wharf work, stowage; insurance, forms and accounts, and charters. Most phases and problems are fully covered, and the timely and able work not only informs, but stimulates.

Features of shipbuilding.

## Synchronous Motors— why used and where

REALIZATION of the benefits of synchronous motor drive to practically all classes of industry today has been established by the unexcelled performance of this equipment in thousands of applications.

The continued maximun efficiency and durable operation of the synchronous motor have demonstated their dollar-earning and dollar-saving qualifications in Steel Plants—Railroad Shops —Paper Mills and numerous other industries—where greater and more uniform production has been obtained at lower maintenance cost.

In addition to carrying a load, the synchronous motor is an efficiency guide to the power factor of the distribution system —bolstering up the laggard that eats into profits, cuts down output, and overworks machinery.

The recognized merits of the synchronous motor tell *why* you should use it. Ask specialists of the General Electric Company *where* its application fits your particular needs. Bulletin No. 41310 gives detailed uses of synchronous motors, and will be sent on request.

ASK YOUR CONSULTING ENGINEER

## For 70 Years

THE various industrial piping systems listed below are designed and installed by us. They are the logical outgrowth of a business effort directed specially for 70 years to the problems of industrial piping equipments.

The experience so gained and the organization thus developed can, we believe, be of paramount importance to those seeking a distinctive service in any of these lines.

Automatic Sprinkler Systems Steam, Hot Water and Gas Heating Power and Related Piping Process Piping of all kinds
Pipe Bending, Threading and Fabricating Fittings, Pipe, Valves Welding Compressed Air Lines Water Supply Systems Hydraulic Piping
Gordon Dryers Safety Fuel Saver Constant Level Size Circulating Systems Piping for Acids and Alkalies

Entered as second-class matter June 18, 1879, at the post office at New York, N. Y., under the act of March 3, 1879.

IN the bearings sponsored by **SKF** its type of anti-friction bearings have been developed to their highest perfection. And **SKF** further provides an engineering service not only to assure to itself proper application and use of **SKF** marked products but to help the buyer to fully capitalize the mechanical value built into each device. This service is freely offered and is being continually broadened and advanced by laboratory research that is international in scope. You are assured a similar service behind every product bearing the mark—

# SKF

***Among these products now offered are:***

Single row deep groove ball bearings
Double row self-aligning ball bearings
Thrust bearings
Steel balls

**The new "Indiana"—Our latest design of battleship, one of a class of six**

## The New Battleship "Indiana"

IN our issue of November 13 we described and illustrated the "Tennessee," which, with her sister, "California," will be the last United States battleship to carry as her main armament the 14-inch gun. The Navy Department has done more or less work upon our next class, consisting of the four battleships of the "Maryland" type, which will be the first to mount the 16-inch gun. In size these ships will be about the same as the "Tennessee." The principal difference will be that they will mount eight 16-inch guns in four 2-gun turrets instead of twelve 14-inch guns in four 3-gun turrets. The names of the vessels of this class are: "Maryland," "Colorado," "Washington," and "West Virginia."

The fine illustration shown above represents the latest class of battleships to be designed by our navy. Six of them are proposed, namely, "Indiana," "Iowa," "Massachusetts," "Montana," "North Carolina" and "South Dakota." As it will be evident from the details given below, these will be the largest, most heavily protected, most heavily armed battleships that have yet been designed for any navy. The length between perpendiculars will be 660 feet, and the length overall, 684 feet. For the first time in our navy, the beam will exceed 100 feet, the exact measurement being 105 feet. This is the practicable limit, as determined by the usable dimensions of the Panama Canal, which has a clear width in the locks of 110 feet. It will be seen that there will be a clearance of only 2½ feet on each side when one of these vessels makes the passage of the canal locks. The mean draft will be 33 feet and the normal displacement with a two-thirds supply of stores and fuel and a full supply of ammunition on board will be 43,200 tons. The full load displacement will be in the neighborhood of 45,000 tons. The motor power consists of twelve White-Forster oil-fired boilers and two sets of Westinghouse turbo-electric drive, and the current will be generated in two main generators and distributed to four motors on the four propeller shafts. The estimated horse-power on trial or, to be more accurate, the shaft horse-power is 60,000 and this is expected to give the ships a trial speed of 23 knots.

Particular attention has been paid in these ships to the protection of their stability and flotation. To safeguard against torpedo attack below water, the space between the outside skin of the ship and the interior hull containing the magazines, boiler rooms, engine rooms and steering gear, is divided by several, continuous, watertight, vertical walls or bulkheads of steel, which extend unbroken practically from end to end of the ship. The bottom edge of these bulkheads is riveted to the inner floor of the double bottom. The upper edge is riveted to the under side of a heavy steel protective deck, located at the water line. Intersecting these longitudinal bulkheads at frequent intervals are transverse bulkheads, which extend from the outer skin of the ship to the bulkhead enclosing the engine and boiler rooms, magazines, etc. Thus, the whole of the elements of the "Indiana" which are essential to her proper functioning both as to speed, maneuvering and fighting, are surrounded by a vast multi-circular, watertight, and immensely strong steel cofferdam which, it is believed, is so efficient that the new "Indiana" can take the blow not only of one but of several torpedoes without being sent to the bottom. Coupled with this is an exceedingly powerful pumping plant with connections which would enable any portion of the ship to be drained of inflowing water. So much for the anti-torpedo protection.

For protection against gunfire, the "Indiana" carries a belt which extends from well forward on the foremost turret to well aft of the after turret, and reaches from several feet below the waterline up to the gun deck. The thickness of this armor has not been disclosed. It is not less than fourteen and may be sixteen inches. The protection to barbettes and turrets is on the same generous scale. Associated with this side armor are several steel decks, designed to exert sufficient retardation upon plunging shell fire, to set off the delay-action fuses and reduce the shells to fragments before they reach the protective deck.

The main battery of these ships has been planned on the same liberal scale as every other element. It consists of twelve, 50-caliber, 16-inch guns, mounted in four 3-gun turrets. The new 16-inch is an exceedingly powerful weapon. It is about 70 feet in length; it weighs over 130 tons, and it fires a shell weighing 2,100 pounds with an initial service velocity of about 2,800 feet per second. Its maximum range is so great as to exceed visibility from the firing ship, and, consequently, the fire will have to be spotted and directed for these extreme ranges from spotting airplanes flying above the enemy. The firing of these guns will be done upon the director-fire principle. The traversing and elevation of the guns will be determined from fire-control stations at the top of the cage masts, and no longer will the gun pointer stand at each individual gun with his eye glued to a telescope the cross hairs of which he endeavors to keep upon the waterline of the enemy ship. All this will be done by an officer using his single directorscope at the top of the mast. There are two fire-control stations, one at the top of the fore, the other at the top of the main mast. Each has two enclosed decks, the upper deck for the control of the main batteries and the lower deck for the fire-control of the secondary battery which consists of sixteen 6-inch, 53-caliber guns. These guns are arranged mainly in sponsons on the main and on the spar decks. Four are located forward in sponsons, abreast of the foremost and navigating bridge; eight are arranged in superposed sponsons in the after part of the super-structure, and four others are mounted in the open, two on each beam, abreast of the navigating bridge. There will also be four 3-inch, 50-caliber, anti-aircraft guns, and two submerged 21-inch turbo tubes will be carried. At present prices the cost of each of these ships will be over 40 million dollars.

The most novel feature, and one which will readily distinguish these ships from others of the navy, is the curious bifurcated smokestack. The uptakes from the boilers lead two large transverse flues at each end of the boiler rooms, and from the center of these rise two semi-circular, curved smokestacks which are drawn

## To Save Our Shipping Fleet

As a result of the investigation of the Shipping Board operations, the public, no doubt, is by this time pretty thoroughly discouraged, if not disgusted. The revelations of incompetence, extravagance and dishonesty on the part of contractors, climaxed by the statement of one of the Shipping Board's leading officials that no less than two billion dollars has been wasted, is one of the most humiliating disclosures in the whole history of this republic. The mitigating fact, of course, is that the ships were built in wartime as a war measure and under conditions quite unprecedented in the history of merchant shipbuilding. The fate of the war, and therefore of civilization, hung upon the question of our ability to build ships faster than the enemy could sink them. You cannot conduct industrial operations under such conditions and expect to realize the economies which are possible in shipbuilding under peace conditions. This fact must never be forgotten in passing judgment upon the amazing extravagance which marked the operations of the Shipping Board up to the time of the armistice. No such plea, however, can be made in extenuation of the continuance of these conditions in times of peace.

It is futile, however, to repine over the folly and blundering of the past. The question confronting the nation is what to do today in straightening out this enormous tangle. We should lay to heart the outstanding lesson of the whole thing, which is that Government operations of utilities are always extravagantly costly. It was the enormous extent of the Shipping Board's operations that brought this fact home to the public with startling and stunning force. So, the very first thing to be done is to get these ships out of Government control and place them unreservedly in the hands of private operators. They should be sold at once, and when they have passed into the hands of the private owner, he should be left to run these ships according to his own knowledge and judgment.

Long before the armistice, Mr. Hurley, then chairman of the Shipping Board, strongly advocated this policy. Had the ships been sold at the close of the war, when there was an urgent demand for shipping and a scarcity of bottoms to carry the world's commerce, the United States Government could have sold these vessels at the then prevailing high rate, and the loss per ship would have been no more than reasonable. To a certain extent this policy was inaugurated and certain valuable contracts had been drawn up and were practically ready for signature, when proceedings were interrupted by the anti-ally propaganda of a notorious newspaper, and the negotiations fell through.

Since those days the inevitable fall in the price of ships and in freight rates has come about, with the result that the Shipping Board's vessels can be sold today only at an enormous loss, and this at a time when a large portion of its fleet is idle for want of freight.

The investigation above referred to has disclosed that many ships are being operated very expensively and wastefully. There seems to have been no proper system of accounting, a fact of which the grafter or the scoundrel, wherever he has happened to be, has taken the utmost advantage. Matters cannot go on as they are. There is call for instant and sharp decision. If you ask the experienced shipping men of the country, you will find them practically unanimous as to policy. They will tell you that we should sell the ships at once for what they will bring; that they should be sold to experienced shipping companies who will know how to run them to the best advantage; and that the relation of the Government to our new merchant marine should be the same as that which it holds to any great American enterprise—a relation advisory, helpful, and protective.

## Our New Army

WHATEVER may have been the differences of opinion on Mr. Baker's policies preceding and during the war, there was a consensus of opinion as to the great ability he displayed in presenting any debated subject—the facility with which he could unravel a complicated question and present it in clear and forceful English. The same quality is displayed in a marked degree in the annual report of the Secretary which has recently come to hand. No one can read this report in full, or even somewhat cursorily, without having a very clear idea as to what has been accomplished in the reorganization of our Army.

Mr. Baker tells us that the Army is essentially a new army, not merely another army from that which existed prior to the war, but new in its attitude toward the country and the country's attitude toward it. He claims that the extent to which a new era has dawned for the Army is shown by the results of the Army recruiting. We are assured that the difficulty in securing the necessary enlistments for our small prewar army has in large part disappeared; and, although the stimulus of the active operations of war has now entirely disappeared, the total strength of the Army on November 3, 1920, was 213,067.

We are not surprised to learn that the one-year enlistment period which was authorized by Congress has failed to give results, and that from the point of view of the efficiency of the Army, one-year enlistment periods are of little value. Short term service with the colors, which might serve under a universal training system, in the nature of things can never produce the efficiency which is necessary in the troops of an enlisted regular army. The term of enlistment should be lengthened.

In reviewing the military activities of this country since 1776, the Secretary tells us that, in spite of the fact that the United States is the most peace-loving of all nations, it has been engaged in major, domestic or foreign wars about one out of every four years during that long period. From this he draws the conclusion that while we do not need a great standing army, we must take the world as we find it and try to make it what it should be. Hence, we must have a body of trained men large enough in numbers to be an effective working model upon which great armies could be swiftly built in case of an emergency. A justice-loving people, says the Secretary, may be forced by tragic necessity to resort to war; but it is not right to ask its sons to fight its battles out-armed and out-shielded by their adversaries.

We are told that the War Department in its study of the lessons of the World War has proceeded on the accepted theory, that the infantry remains the backbone of the Army; although at the same time certain other arms of the service were greatly increased in importance by the swift developments of the conflict now past. Fundamental changes in armament have taken place and many of the instrumentalities devised are apparently only at the beginning of their development.

In this connection, we draw attention to the fact that one of our contributions to the development of war weapons was the motorization of artillery and transport. While the allies had done some work along this line, our Ordnance officers worked out a very ambitious system for the complete motorization of artillery up to and including the very largest types of guns. The same thing was being done with transport, and it is our hope that the policy will be followed out. Although it is true that the infantry have maintained their position as the backbone of the Army, it is also certain that the necessity for close coördination between infantry and artillery, not merely field but also heavy artillery, was greatly emphasized on the fields of France and Flanders. The army which possesses the most mobile artillery and transport, other things being equal, will hold a commanding position.

A well-earned tribute is paid by the Secretary to the work done by American women in the war. "All over France during the war," says he, "it was possible to find these serene, dignified, and helpful women; and I know no more knightly fact than that, from the beginning to the end of that great experiment, there is no recorded instance of an indignity or an incivility from a soldier to a woman." This is a fine tribute to the women who served in the various agencies built up around the soldier and his needs.

## Why Is A Patent?

THE governmental departments that act as agencies for the collection of the revenue—the customs and the internal revenue—are of course expected to bring in more money than they pay out.

A casual observer would not hesitate to say that no other governmental bureau could possibly be expected to show receipts in excess of expenditures. The Government is not in business for itself or for a profit—it is in business for all of us and for service. Certainly the War and Navy Departments, that supply us with the service of protection, are not to do this at a profit. Surely the Department of Justice does not expect to create a financial profit out of the pursuit and conviction of moonshiners and conspirators in restraint of trade. The Departments of the Interior and of Agriculture and of Commerce and of Labor like to feel that the American people as a whole, through taking advantage of what the departments do for them, save and win sufficient in the course of a year to make the departments a net cash asset to the country at large. But if you asked the Chief of the Bureau of Plant Industry or the Commissioner of Lighthouses or the Director of the Census or the Public Printer why their offices do not show an operating profit, you would get a properly indignant reply.

Even the Post Office, doing business on such a vast scale and at such rates that a profit from operations would seem well-nigh unavoidable, has usually managed to avoid this, and when it has so far transgressed governmental properties as to take in more money than it paid out has promptly made arrangements to remedy this condition by enlarging the scope of its nonprofitable services. Here, as in general throughout the Government, the whole theme is to give service—service that shall be profitable to the country at large, and for which the country at large, rather than the direct beneficiary, therefore pays in taxation.

To this benevolent policy, however, there is one shining exception, as pointed out by Mr. William Wyman on another page. The Patent Office, from almost its inception, has been conducted at a direct profit. For some mysterious reason it always is assumed, whenever the needs of this office are being considered, that of course the revenues from the office will meet all the expenses of conducting it, and a little bit more. We wonder what would happen if our courts were conducted on the same principle—if the question of adding a needed member to the Interstate Commerce Commission or bringing the salaries of the Justices of the Supreme Court up to a proper basis was made to depend upon the extent to which additional funds might be obtained through a revision of court fees and fines?

The fundamental fallacy seems to be that the Patent Office is selling something to the people with whom it deals, and that they must pay the cost of that thing. We have exposed this fallacy often, and shown clearly that the whole position of our country in the world depends upon the supremacy maintained by our inventors in spite of every discouragement.

The Patent Office is not selling goods to inventors. It is granting to inventors what is theirs by virtue of a provision in the compact known as the Constitution of the United States. If it is intended to withdraw this as a right, and replace it by a privilege to be sold only to those who can pay for it, let us come out in the open and amend the Constitution; let us state explicitly that, like France, we regard the inventor solely as an object of taxation and after we have got out of him all we can, do not care what becomes of him. If it is not intended that this be the basis of our patent system, let us put the Patent Office on a footing of equality with the rest of the Government.

## Naval and Merchant Marine

**Italian Flotilla Leaders.**—In the opinion of some authorities, the latest Italian flotilla leaders to go into commission are the most powerful in the world. With a displacement of from 1,900 to 2,200 tons, they are comparable to the British "Scott" class. Three of the boats mount three 6-inch and four 3-inch guns, and the fourth carries six 4.7-inch guns, which may be compared with the armament of five 4.7-inch guns in the latest British fotilla leaders. The contract speed of these boats, 35 knots, has been exceeded.

**Improved Gunnery in the Navy.**—Analysis of the gunnery exercises of the American Navy during the past year shows that the greatest progress toward efficiency was made by vessels of the battleship class, due to the larger number of men aboard such ships and the comparative stability of the personnel. The Navy Department considers that battleship gunnery is at present about equal to that of foreign battleships. It is believed that next year vessels of other classes will be brought up as regards gunnery to the level of our battleships.

**The Minimum Requirements of the Modern Dreadnaught.**—Speaking editorially the *Naval and Military Record* says that British naval opinion is almost unanimous as to the material elements which qualify a capital ship for the first rank. These are: First, a main battery of not less than eight guns nor of less than 15-inch caliber; second, for battleships, armor protection that will resist the heaviest armor-piercing shell at ranges exceeding 12,000 yards; third, an all-round bulge defense against torpedoes; fourth, for battle-cruisers a sea speed of not less than 30 knots.

**British Dominions and Navy Policy.**—The various British dominions, and particularly Canada, New Zealand and Australia, are giving much attention to the question of naval defense. There is a tendency to muster out the older units and keep in commission only the latest types of warships. The question of future increases is awaiting the decisions of the Meeting on Imperial Defense, which will be held next year, at which all the dominions will be represented. It is likely that the plan of imperial defense drawn up by Lord Jellicoe will be accepted with certain modifications.

**Monument to Dewey at Manila.**—Rear Admiral Casey B. Morgan, Commandant of the naval station at Cavite, P. I., in a letter to the governor of the Philippines, refers to the absence of any monument or public improvement in the city of Manila bearing the name "Dewey"; which lack of suitable civic recognition has been a matter of wonderment and amazement to him and to other officers who have been associated with these islands since the earliest days of our occupation. It is amazing that such neglect of the deeds of this great naval officer should exist.

**Admiral Benson to Masters of Ships.**—Admiral Benson has recently made public a message to all seafarers of the merchant marine, in which he draws attention to the reduction in ocean freight movement and makes an appeal for a spirit of coöperation under the present conditions, so that foreign competition may be successfully met. He urges masters and chief engineers, port captains and port engineers "to take the utmost interest in the operation and proper repair of the vessels in their charge." He urges them to keep their ships in seaworthy condition, to effect quick turnaround, to reduce the cost of repairs, and avoid overtime. He reminds them that without such increase in efficiency an increasing number of vessels must be tied up.

**Battleship Versus Torpedo Plane.**—Commenting on certain articles by "Quarterdeck" in the *New York Tribune*, in which the abandonment of the superdreadnaught, if not the dreadnaught itself, was advocated, Rear Admiral Fiske says that most of the men who oppose the strenuous development of aeronautics have not carefully studied its possibilities. He agrees with "Quarterdeck" that this is the time to "stop, look, listen," and study thoroughly the possibilities of the new art. He believes with many others that aeronautics is destined to bring about "a revolution in warfare, in comparison with which the revolution brought about by the invention of the gun was like a vaudeville performance." Pretty strong words these for an admiral! At the same time, no naval man is better qualified to speak on this subject. Admiral Goodrich writes to the same paper that if he understands "Quarterdeck," this is the moment for careful investigation, for which ample time exists. He believes that it is not the time for continuance and enlargement, and the present building program may be found to be unwise.

## Astronomy

**The Laws Observatory** of the University of Missouri, erected in 1853, has been torn down, and a new building is being erected to replace it about half a mile south of the former site.

**Periodic Variations in the Brightness of Jupiter,** due to the different markings presented to us in the course of the planet's rotation, though necessarily very small, are within the range of observation of the photo-electric cell. At the Berlin-Babelsberg Observatory P. Guthnick found by this means last December and January a variation having an amplitude of 0.14 magnitude. This variation had, however, diminished to 0.04 magnitude a month later.

**The Warner and Swasey Observatory.**—On October 12, 1920, occurred the formal dedication of the fine observatory presented to the Case School of Applied Science, Cleveland, by the Warner & Swasey Company, and called in honor of the donors the "Warner and Swasey Observatory." An address was delivered by Director Campbell, of Lick Observatory. The new observatory contains a library and a full instrumental equipment, including a 10-inch refractor, of which the object-glass was made by Brashear and the mounting by Warner & Swasey.

**Warner & Swasey.**—The name of this American firm of telescope-builders is a household word among astronomers, who will be glad to add to their libraries a booklet which the firm has published on the occasion of its 40th anniversary, giving a history of its development from the usual small beginnings. Many astronomers will be astonished to learn that telescope-making is almost a negligible fraction of the business of this great establishment, the chief product of which is the turret lathe. Similarly, meteorologists who visit the "Belfast Observatory" factory of Messrs. Julian P. Friez & Son, in Baltimore—remarkable for its architecture and appointments, as well as for the work done there—are usually much surprised to discover that the making of meteorological instruments is a side issue in the business of the concern.

**Longitude Determinations by Airplane.**—M. Paul Ditisheim has recently published the results of his latest experiments in determining differences in longitude by means of chronometers carried in an airplane; the experiments in this case having been made in May, 1920, between London and Paris. Twelve small "deck watches" were used in the experiments, after having undergone rigid tests at the National Physical Laboratory and at Greenwich Observatory and having proved to be of exceptional accuracy. These were carried 5 times by airplane between the English aerodrome at Croydin and the French at Le Bourget, the trips between the aerodromes and the observatories of Greenwich and Paris, respectively, being made in automobile. On these journeys the time-pieces were carefully packed in a valise, which M. Ditisheim, with the aid of a spirit level, maintained in a horizontal position. Corrections were applied for temperature and altitude. The mean result of all the determinations was 9 m. 20.947 s., while the mean of the best previous determinations by other methods is 9 m. 20.952 s.; in other words, the airplane method gave a result for the difference of time between London and Paris differing only .005 second from the standard value.

**Nova Cygni No. 3,** which was of magnitude 3.5 when discovered by Denning on August 20, 1920, and rose to a maximum brightness of 1.8 on August 24, remained visible to the naked eye for less than a month. It is gratifying to record that members of the American Association of Variable Star Observers obtained 287 observations of the brightness of this star, covering every day of the month during which it was a naked-eye object, and, at first, almost every hour. Early in November the star was still visible in small telescopes, being of about mag. 9. The history of the star before August 20 has been published by M. Felix de Roy in the *Observatory*. It is not found on a photographic plate taken June 3, 1905, which shows stars down to the 16th magnitude, nor on a plate of the same region taken July 20, 1920, showing stars down to the 11th magnitude. A Harvard plate taken August 9, 1920, including stars down to the 9th magnitude, does not show the nova, but appears as a 7th magnitude star on a plate taken by Nils Tamm, in Sweden, August 16, and as a star of mag. 4.8 on a Harvard plate taken August 19, the day before its visual discovery. M. de Roy calls attention to the fact that novæ have, of late, been more plentiful than comets, and that four of these objects are now visible in telescopes of moderate aperture: viz., Nova Cygni No. 3, Nova Aquilæ No. 3, Nova Lyræ and Nova Ophiuchi No. 4.

## Engineering

**More Power from Water Resources.**—A large hydroelectric plant of 20,000 horse-power has recently been completed by a French hydroelectric company. The new plant is located at Seyssel, Haute-Savoie. Importance is attached to the completion of this project because of the present scarcity and high price of coal, and likewise because of the effect it will have toward encouraging similar undertakings in France. The new plant is equipped with four turbines, each capable of developing a force of 5,500 horse-power. It is proposed to install another turbine at an early date, and thus increase the production to 27,000 horse-power, an amount that equals almost one-third of all the energy consumed under different forms by the city of Lyons.

**Pressure of Concrete on Forms.**—A pressure-gage devised by A. T. Goldbeck and used for the last few years in measuring earth pressures behind retaining walls and under fills, has been applied successfully to the measurement of the pressure of concrete on forms embedded therein. The gage consists essentially of an air-tight metal cell having a circular weighing face 10 sq. inch, in area, according to the *Engineering News-Record*. The concrete pressures against the face of the cell are balanced by admitting compressed air to the inside of the cell. When the pressures are balanced an electrical contact is broken which extinguishes a light and signifies that the pressure shown on the gage connected with the air pipes is equal to the pressure of the concrete.

**Making the Most of Natural Reservoirs.**—From Australia comes the news that Torrumbarry weir will immediately serve an important purpose. At the present time large areas in Victoria are served by natural reservoirs known as the Kow Swamp and the Lerang Lakes. When the Torrumbarry weir is completed the level of the river will be considerably raised, and it will become possible to replenish these natural reservoirs when desired. Another important work contemplated at an early date is the construction of a weir for the diversion, when necessary, of waters into Lake Victoria. This lake provides one of the finest natural storage basins along the whole length of the river. The object here will be to fill this basin during times of plenty and then, as the river later recedes, to discharge its contents back into the river for the use of the settlements in South Australian territory. Thus the water instead of being allowed to escape will be regulated to suit the requirements of the irrigation settlements.

**Concrete in Cold Weather.**—This is the time of the year, says *Engineering News-Record*, when warnings about frozen concrete should be more freely given. When it is definitely and continuously cold only the most ignorant and careless will attempt to make concrete and remove forms without due respect for freezing, but now the warm mid-day is apt to make the constructor forget the cold mornings and cold nights which retard setting just enough to reduce strength below the safe limit. An added warning may be worth while. The only certain way to insure against cold weather in concreting is to provide heat—heat in the aggregate and in the water and heat in the structure during the setting period. There are chemicals which lower the freezing temperature of concrete, but their advantage is indeterminate and at best small. Little dependence can be placed on them as a total defense. They may serve as a partial defense when temperature reductions are small, but if their use leads to neglect of more certain precautions they inspire an unwarranted confidence.

**Maintaining the Dirt Road.**—There is little local stone in the Canadian province of Saskatchewan, hence the question of roads resolves itself into importing supplies at a considerable expense or resorting to dirt roads. As far as rural roads are concerned, the cost of the former practice is prohibitive, and the dirt type has been widely adopted. Recognizing the limitations of an earth road with regard to the permanency of its surface, the question of providing a serviceable earth road becomes largely a question of maintenance, and because of the quick deterioration of such a road, especially in wet weather, its maintenance must be continuous. This, we are told by the *Road-Maker Excavator and Grader*, can be accomplished effectively and cheaply by a proper use of the road drag. The work has to be done repeatedly, and, although there is little improvement to show for two or three draggings, a season's work gives manifest results, and the improvement continues with each successive season that the dragging is kept up. The work in Saskatchewan has been encouraged by the institution of an annual competition. The average cost of road dragging in 1914 was $6.28 per mile; in 1919 $9.04 per mile.

# The World's Greatest Shipping Terminal?

## Or Will Hog Island Merely Stand as the Record Junk-Pile of All Time?

By William Benjamin West

*ADVERTISEMENTS appearing in the daily papers recently indicated that Hog Island is on the market. We have seen what happened to other items of war-time salvage of which the Government countenanced the dispersal or sale. But Hog Island, it seems, ought to stand in a class by itself, as the one by-product of the war which possesses inestimable value to the American people. Whether it is sold or not, every precaution ought to be taken to see that it remains in use to the greatest possible extent of its vast capacities.*—THE EDITOR.

THE plan of building fabricated ships had been advocated by leading engineers for years, and when it was found that we were compelled to have ships built within a short time, the construction of ships in this way seemed the only thing to try. But existing yards were not adequate and a new yard had to be built.

Through authorization from the Federal government, a careful investigation of all the proposed sites for a plant was made. After considering the different prospective places, Hog Island, a barren waste of land about 10 miles from City Hall, Philadelphia, was finally selected for the largest of these yards.

The main aim was to build ships, build many and build them quickly, for our country was needing them, and needing them badly, so nothing was spared. What can be seen now at that shipyard is evidence that something must have been going on there during our time of belligerent activity. Approximately 35,000 people were employed in the construction of the plant. Personal observation as to the organization and detail that is carried out at present, even though the war is now over, leaves the impression that the operation of the yard was carried out as efficiently as could have been done under the trying circumstances.

From a barren island of waste land in the summer of 1917 to the largest shipyard in history one year later, in spite of the terrible weather conditions encountered, and almost unsurmountable difficulties overcome, is a record seldom if ever equaled in the history of American industry. And Hog Island has continued to build ships after we withdrew our forces from France and the records show that her trend of efficiency has constantly been upward ever since the present management took charge.

After the first ten ships were constructed the unit cost continued to decline and finally the latter part of the programme was completed at considerably below the unit cost and in a part of the time spent on the first lot of ships. However, it is not for the writer to either uphold or criticize certain phases of the work at Hog Island in this article, but rather to describe certain interesting features of its construction and outline the general plan of operation.

The original area of Hog Island was 846 acres. The purchase price of this tract was $1,706,000. In 1918 an addition of 81.14 acres was made to this by the purchase of what is known as the west impounding basin at the west end of the original property on the water front, for the purpose of pumping from dredging in the wet basin.

With the construction program fully completed, there are 50 shipways at Hog Island. They are divided into 5 groups of 10 ways each. The total area of the 50 ways is 1,529,560 square feet. Some of these ways are of wood and some of concrete construction. The piers between ways are 37 feet wide and vary in length from 132 to 324 feet. There is a wide pier between each group of 10 ways which is 142 feet wide. The total area of the ways and piers is 442,193 square feet. There are 7 piers 100 feet wide and 1,000 feet long (on the short side of the pier) in the wet basin. It is these piers which certain authorities are recommending for use as a terminal at Philadelphia after the closing down of the shipyard. These 7 piers which are used for outfitting the ships after they are launched have a total area of 747,271 square feet.

The administration buildings, office buildings on ways and elsewhere, have a total area of 1,200,000 square feet. The utility buildings, fire houses, electric substations, guardhouses, water stations, etc., have a total area of 150,000 square feet. There are 90 acres of steel storage yards, 58 acres of equipment storage yards, and 5 acres of coal storage yards. The total area of all these yards is 153 acres.

There are two separate and distinct water systems at Hog Island, a high-pressure system for fire protection and industrial use, and a domestic system for drinking water, etc. The high-pressure system consists of two pumping plants. The capacity is 19,000 gallons per minute; normal pressure 62.5 pounds; fire pressure 125 pounds (with pumps connected in series). There are 270 hydrants and 86,000 feet of piping from 2 to 16 inches in diameter.

The domestic system consists of one pumping station and one filtration plant. Its capacity is 2,000,000 gallons per 24-hour day. The source of both systems is the Delaware River. The filtration system is the rapid sand gravity type through which water is sedimented, filtered, and chlorinated. This system has a storage capacity of

## From Wood to Cloth

By Samuel J. Record
Professor of Forest Products, Yale University

CLOTH made from wood is of interest in this country chiefly because of its novelty. A few suits of "wooden" clothes have been imported from the Central Empires and during the "over-all campaign" against the high price of wearing apparel considerable attention was devoted to them because of their cheapness.

Low first cost is about all that such clothes have to recommend them, except as a passing fad, or in times of great emergency when cotton, wool and other standard textiles are wanting. Germany experienced such an emergency and wood-paper textiles proved to be better, very much better, than nothing. The users of such material came to it with suspicion and, for the most part, had as little to do with it as possible. The principal objection to it was that it wouldn't wash and the objection was well founded, especially at first.

Wood is a fibrous material and its essential constituent is the same as that of cotton, namely cellulose, though not in nearly so pure a state. The Germans were able to purify wood cellulose, however, and use it as an acceptable substitute in the manufacture of gun cotton. Wood has also been used for years in the manufacture of artificial silk, an industry which has become of very great importance. In the latter use as a textile material, all trace of the fibrous structure of the wood is obliterated and an entirely different substance is obtained.

It is a comparatively simple matter to reduce wood to its component fibers since the cementing substance that holds them together is readily dissolved by certain acids and alkalies without material injury to the cellulose of the fibers. In spruce wood the length of fibers varies from one-tenth to one-fourth of an inch with an average of about one-eighth of an inch. In some other woods they are a little longer or a little shorter, but apparently too short for spinning directly into yarn or thread, though the Germans claim to have devised a method for doing it. The usual way is to convert the fiber into paper and then spin paper strips into yarn.

In paper-making wood is reduced to fine fibrous pulp, which is felted together into a sheet and ironed down. Different kinds of paper vary enormously in their strength, toughness, resistance to wetting, etc. News-print paper, which is very weak and brittle, is made mostly of ground-wood pulp, that is, the wood is reduced to

## A Giant of Old

By J. Flagler Wright

THE modern turbine water wheels differ from old-time water wheels particularly in the fact that the new machine receives power water around pretty much the whole of the circumference, whereas the old style wheels received it either at a single point or else through a limited arc. No doubt, the extension of the region of application of power water is a principal factor in the efficiency of the more recent appliance. However, the old wheels deserve our respect. It is also possible that they embodied features which are capable of development under present-day circumstances.

One of the most notable of the old machines was the old Burden Water Wheel at Troy, N. Y. This fellow was the greatest of all American water wheels belonging to the period preceding that of the hydraulic turbine. The diameter of this giant was about 60 feet. It was of the over-shot type. That is, the water impinged on or near the summit of the wheel. There was a central hub to which 264 iron rods were attached. These extended in approximately radial directions, somewhat like the spokes of an ordinary carriage wheel. These were, at their outer ends, secured to the wooden rim.

Unlike a good many water wheels of the older time, the Burden wheel did not exert its drive through a central, or axial, shaft. Instead, the drive was effected on the two sides near the periphery. That is, a gear rim of the spur type was arranged on the two sides of the water wheel. The diameter of each was 56′ 4″; so that the drive was effected by wheels almost as big as the water wheel itself. This arrangement of peripheral drive eliminated torsion troubles with the main shaft. By using what was in effect a big spur gear on both sides, the wheel was stressed evenly. The big gears each meshed with a small spur gear on a shaft. The shaft was arranged in front of the face of the great wheel and about half way down between the level of the center and the level of the bottom. On one side, the shaft was prolonged greatly. At the end was mounted a big spur gear called the bull wheel. It meshed with a small gear on the same shaft with a 20 foot flywheel. By means of a bevel gear turning with the flywheel and a second bevel gear on a long main shaft, the latter was rotated. This mainshaft, as perhaps the reader has already surmised, was set at right angles to the axis of the water wheel.

The water to drive the wheel was

# The Needs of the Patent Office

## Results of the Insistence that This Most Vital Government Bureau Pay an Operating Profit

By William I. Wyman, Chief Clerk, U. S. Patent Office

THE imperative need of the Patent Office is a new attitude. The argument that has most been used to obtain support for its requirements is that it pays a profit into the Treasury. That the Office makes a profit is conclusive that the inventor is being deprived of something due him. But the fact that should be of the most signifisance is that the Office, as the center of the patent system, is a vital factor in the industrial progress of the country; and its needs should be treated with that consideration solely in mind. The general government pays out scores of millions of dollars for education, scientific research, promotion of agriculture, publications of more or less cultural value, and for various like purposes. But for the medium that is the most direct incentive for increasing the industrial capacity of the people, the government sees to it that it does not spend a red cent. In fact, it plays safe by assuring to itself that the Patent Office shall always be conducted at a profit.

The obvious and more immediate needs of the Patent Office are more room, better equipment, and a larger and more adequately paid force. The building is crowded to-day. There is practically no room for the expansion for the business and the records. The examining divisions are jammed, the files occupy every nook and cranny of the building, the clerks do work in close and uncomfortable quarters, and the library, search and record rooms are filled to capacity. Immediately there should be planned provision for a new building or for enlarged quarters. Even if more room were authorized at once, the pressure of constricted space would become critical before the additional accommodations could possibly be made available. The necessity for quick action is, therefore, very plain—the penalty for delay very apparent.

The equipment of the Office is antiquated and insufficient. The furniture, filing cabinets and shelving, and general office appliances are about the worst in the government service and require modernization and extension. This is particularly true of the storage of copies of patents, the Scientific Library, the records in the manuscript and assignment divisions, and the files throughout the Office.

The clerical force is at present inadequate to do the business of the Office. A 15 per cent increase in numbers with a fair advance in salary to hold and acquire good personnel material would be sufficient to relieve the present unsatisfactory status. As for the technical corps, (the examining service of the Office) a much larger increase in numbers than is provided in the Nolan Bill, now in conference, is desirable if any permanent improvement is to be secured in the character of the examination. If more than a fair scrutiny of the art is to be observed, if something approaching a critical examination of the vast printed records of the advance in industry is to be undertaken, the field of search must be much more limited to the individual examiner and he must be given much more time to study the records and make up his decisions. Especially is this the case in the more technical arts, such as the chemical, electrical and process departments.

It goes without saying that the rapid overturn of the scientific men in the Bureau is disintegrating and disruptive in the highest degree. Any advance in salary that would retain a substantial percentage of the large numbers who now resign to receive greater compensation in private practice would save the industries of the country many fold the advance in pay. At present, this is the most disturbing situation in the Office, but may be remedied if the Nolan Bill (referred to above) passes Congress in its original shape.

These are the most obvious inadequacies and they require immediate remedial treatment if the Office is to perform its most elemental functions with even a minimum amount of satisfaction. Failing this, in any particular, the public must face a continuance of the irritating, insufficient, dilatory and costly conditions which now entail such a needless hazard upon American industrial progress.

The requirements just specified are those necessary for merely carrying on the ordinary functions of the Office in accordance with the accepted standards of the last two generations. To correct the glaring deficiencies so enumerated would merely give the public the service it normally expects and is entitled to. These urgent needs attended to, the public would then receive expeditious responses to their inquiries, and the aggravating and inadequately paid force and poor equipment would be corrected. But the usefulness of the Office is far from being limited by the installation of these merely remedial measures. It can multiply its effectiveness immeasurably through its extension of its functions and changes in its methods.

The Office to-day lacks effective organization. There are 60 or so divisions, about 50 being technical and the remainder clerical. The Commissioner is in direct control of the technical divisions and exercises his administration of the clerical divisions through the Chief Clerk, who, in turn, shares with the primary examiners the control of the clerical personnel in the examining division.

It is utterly impossible with this arrangement for the Commissioner to have an intimate knowledge of the conditions existing in the many units into which the Office is divided. For purposes of administration and to make the actions of the examiners more uniform (now so objectionably diverse) it would appear to be decidedly advantageous to combine the divisions into groups. The associated divisions could be grouped to accord with the related arts. Questions of assigning of applications, simplifying the search, associating the related literature and making available the technical and legal knowledge of the corps, could be more readily disposed of. The files could be kept more systematically and the clerical and messenger work be made more elastic to accord with any change of condition. The executives of the Office could exercise a more intelligent and intimate control over the actions of a small number of large divisions than over a great number of diversified and small units. And that such intimacy of control is needed is well known to all observers and is in accord with general experience.

Another defect in the organization is the mixture of functions exercised by the Commissioner. He is at once the administrative and legal head of the Office, and as the duties in both capacities are heavy and involved, one or the other suffers in their exercise. Without a change of method, such a sacrifice of one of his dual rôles is inevitable. The writer's suggestion is to lodge the entire *active* administration in the hands of the Commissioner and to control the legal program of his office by requiring the Assistant Commissioners, who shall hear *all* cases that come up to the Commissioner on appeal, to report and obtain his approval of all decisions that involve a commitment to any change of legal policy or radical legal action. Those cases that involve the substitution merely of the appellate tribunal's judgment in place of that of the tribunal below could all be tried and decided by the Assistant Commissioners. Only such decisions which would commit the Office to a new course of procedure, or which would constitute leading cases should be referred to the Commissioner for his approval or criticism. Such decisions should be published over the name of the Commissioner and they would comprise the means by which, without undue expenditure of time and labor, he could thoroughly exercise his legal control and leave time for the execution of any administration program, no matter how involved or ambitious.

Inseparably connected with reorganization is adequate room, effectively rearranged to carry forth any advanced scheme. To execute the group plan, to provide that there shall be no lost motion in the movement of the work, to assign and locate responsibility in the duties to be performed, and to bring the clerical divisions into efficient coöperation with the technical departments and into effective relationship with the public require a structure planned on radically new lines. Subsidiary to this, but dependent upon any new plan of building devised, is that of equipment. The means for storing the records and files and for transferring messages and papers could, if comprised of modern appliances, provide for tremendously better service in the way of expedition and accuracy. Especially is this so in the matter of storage of printed copies of patents. These should be placed in a central location according to the stack system, in compact arrangement and in connection with devices to provide accurate placement and quick deliveries.

Without a permanent force no reorganization, no reequipment, will be sufficient. It goes without saying that adequate salaries should be paid to avoid a constantly shifting personnel. It is not too optimistic to hope for such a development in public opinion as will abolish politics in the appointment of the Commissioner. With a comparatively fixed personnel, it is possible to develop an administrative policy and to increase the usefulness of the examiners to any reasonable degree. That deep knowledge of an art that comes from extended practice therein could be made available to the public by such means as the compilation of card indexes, or the publication of brochures on various phases thereof (to mention only a few suggestions that come to mind). With a staff of men attached permanently to the Office, it would be a good investment for the public to assign them at various times to inspect and "live" with the industries in order to acquire the "atmosphere" of their arts and a practical point of view. With a permanent and adequate force of scientific and enthusiastic men, there is almost no limit to the extent of valuable service they could render to the industries of the country.

Another highly desired consummation is the completion of the reclassification and a rapid review of it after completion to iron out inequalities and inconsistencies. Once that is done, and the classification fairly standardized, it is possible to brief the inventions and publish abridgments of them, as is done by the British Patent Office. Or patents unabridged could be bound in classified arrangement and form valuable compendiums of the arts. The last-named service would be particularly desirable, as it would simplify a perplexing branch of the copy-sales activity and would become a double convenience to the public and the Office.

The extent to which the Scientific Library could be improved is limited only by the powers of the imagination. In connection with digests made by a permanent corps of examiners, it could, with a comparatively small additional expense, as appropriations go now-a-days, form a research laboratory for the development of facts on all published subjects pertaining or relating to the applied sciences. It should contain the best and completest fund of scientific information in the world, should have the necessary room and equipment for proper functioning and expansion, and should be provided with expert and adequate direction and assistance.

The Patent Office should also emulate other scientific bureaus of the government. It should get into intimate touch with the people, scientific establishments and the industries. It should have the services of experts in technical specialties at its beck and call and should have laboratories for testing disputed questions of utility of invention. It should issue publications from time to time explaining developments of arts as some of them become unsually active or vital, and should provide, by general and gratuitous distribution in pamphlet form and in popular language, information as to the patent system, the necessity of being capably advised before proceeding with an application, and an indication of the

(*Continued on page 603*)

*THE question has been asked very often of late years, "What is the matter with the Patent Office?" Almost as many different answers have been given as distinct answers. Certainly the Office is ridiculously undermanned and underpaid; certainly it finds it more than difficult to get Congress to pay serious attention to its plaints. Mr. Wyman, we think, puts his finger on the root of the trouble when he points out that where other departments spend and are expected to spend many millions against receipts that are practically negligible, the Patent Office is always looked to for a profit. The Government pays for every conceivable kind of research and investigation and propaganda; but patents, on which our whole industrial system is founded, pay for themselves and pay a profit. We have not space here to discuss this point more fully; we return to it on our editorial page.*—THE EDITOR.

## Recent Patents on Mixed Fuels

AN investigation into the subject of recent patents granted for inventions relating to mixed fuels for internal combustion engines for automobiles and so forth has been made by a Dr. W. R. Ormandy and published as an article in the official organ of the Institution of Petroleum Technologists. The author thinks that an alarming situation has arisen owing to the number of patents now existing, in which there is no real novelty, sometimes even no useful feature, in the invention claimed or in which the "invention" resides in a combination of materials having such well-known properties as to render its feasibility at once obvious to any person having some knowledge of these matters.

The paper refers to the enormous increase in the numbers of installations having internal-combustion engines requiring liquid fuel. A parallel to the present fuel situation is provided by the case of rubber, until the production of plantation rubber was seriously undertaken, and by the existing shortage of the long staple cotton required by the tire industry.

The increasing prices of the liquid fuels required by the motor industry led the author to examine the patent specifications, bearing on this subject, from 1913 onward, to see what evidence there was of an awakened interest in volatile fuels. The specifications bear evidence of the universal assumption that alcohol in some form will be a constituent of the motor fuel of the future. A number of specifications are described in detail. The inventions chiefly consist in the admixture of crude or other alcohol with the well-known volatile hydrocarbons of the paraffin series, known under the generic term "petrol." From one specification it may be gathered that in 1870 it was common knowledge that commercial alcohol containing 5 to 10 per cent of water could be caused to mix with paraffins and similar hydrocarbons in the presence of fusel oil or higher alcohols. Sometimes a "mixing or combining agent," such as fusel oil or amyl alcohol, is added to avoid non-miscibility due to the water present in the commercial alcohol.

A second group of patents has reference to methods of increasing the vapor-tension of alcohol, which is low, especially in cold weather, by the addition of ether, alone or in combination with alcohol and other substances. A third group comprises the addition or admixture of gases, such as hydrogen, the lighter hydrocarbons of the paraffin series or acetylene, to the hydrocarbons of low volatility, so as to lower their ignition temperatures. Sometimes ether, alcohol, or acetone is added to increase the solubility of the acetylene. One specification claims the use of alcohol saturated with acetylene; another the same mixture with the addition of 1 per cent of acrolein as a denaturant.

Thus it appears that patents have been granted for admixtures of bodies, which every chemist knows will mix, and every engineer knows will drive an internal-combustion engine. Such mixtures are, moreover, of obvious application, provided that the ingredients are obtainable at a reasonable price. Many patents have been granted, and, no doubt, many more will be granted for inventions which are matters of common knowledge, presumably because the patent records of the previous fifty years cannot show that anything of the sort has been previously patented. Such patents would not be granted in Germany. Under the amended Patent Act in this country, it is possible to oppose the grant of patents on the ground of the prior publication of the invention in a technical paper, document or foreign specification. The indiscriminate granting of patents for every conceivable mixture of inflammable organic liquids, which might possibly be used as a motor fuel, constitutes a distinct danger to the motor user, motor manufacturer and community alike.

## The Influence of Cadmium on the Properties of Brass

CADMIUM possesses an influence upon properties of zinc and its alloys which may become injurious in certain amounts. A French investigator, M. Leon Guillet, has undertaken to determine the exact quality of this influence with respect to alloys of copper and zinc, and has published his conclusions in *La Revue de Métallurgie* (Paris).

Test pieces were taken from two series of alloys, one containing 70 per cent of copper and the other 60 per cent, the content of cadmium varying from 0 to 4 per cent. These were subjected to mechanical tests, traction, shock, hardness, etc. The following conclusions were arrived at: one per cent of cadmium in brass containing from 60 to 70 per cent of copper does not alter the mechanical properties. Since this percentage is never attained in these alloys constructors need have no fear of them. Examination under the microscope shows that these alloys have the normal structure of brasses and contain no free cadmium. When cadmium is present in more than one per cent the microscope reveals an increasing quantity of free cadmium. The cadmium is separated into filaments which have a tendency to surround the grains of the metal, and when the content becomes very high it forms spherical agglomerations recalling those made by lead in brasses. When this free cadmium appears there is a perceptible diminution in the chemical properties of the alloys.

The influence of the cadmium affects chiefly the resilience which undergoes an abrupt fall, whereas the other properties, especially those concerned in the traction test retain their high value. With a higher content of cadmium the elongations are lessened and soon reach a very low value.

## Filtering by Means of Spun Glass

IN the Gulf Coast oil fields much trouble is experienced with the working barrels being cut to pieces by sharp and exceedingly fine sand, to say nothing of the annoyances caused by the tubing becoming filled to such an extent as entirely to block the rods.

Experiments have demonstrated the value of spun glass as a filtering medium. A strainer was made of pipe of two different sizes, the space between having been loosely packed with glass, and brown settlings and sludges from a Bayonne oil plant used as a test. The finest particles of foreign matter were filtered out, the process also increasing the most minute water globules to the size of a pea, making dehydration much more readily accomplished.

Glass is non-corrosive, its hardness approaches that of sand, and even the finest threads are of sufficient strength to span half-inch openings in a strainer. It can be easily cleaned with gasoline. During the experiments with this strainer, which showed the tendency of the glass to enlarge water globules, another apparatus was tried. A two-inch glass tube was filled with one-eighth-inch glass rods running longitudinally, and the brown settlings were pumped through from end to end. Microscopic water globules were found to increase in size to "slugs" of a teaspoonful, due to the difference in viscosity of the two liquids. It remains only to initiate experiments under working-scale conditions to demonstrate the commercial application of the invention.

## The Rule of the Road

To the Editor of the SCIENTIFIC AMERICAN:

I was interested in your note in the issue of the SCIENTIFIC AMERICAN of October 23rd, dealing with the change of road rule lately adopted by British Columbia. It was obviously inconvenient and unconducive to four horses were harnessed without a postillion to the left when elsewhere in the Dominion and in the United States the opposite is the practice.

At the same time the balance of argument, I venture to think, is in favor of the English method. The latter originated no doubt in the old coaching days when four horses were harnessed without a postillion to the vehicle. Much deftness on the part of the coachman was required to manipulate the long lash of the four-in-hand whip. It never was easy to give a touch to one of the leaders when it required it, but to do so from the left of the box seat would have been an action not only of extreme difficulty to the coachman but of considerable discomfort to his neighbors. The driver would naturally therefore adopt that rule of the road which permitted him at once to keep his right arm free and to judge best his distance from the wheels of oncoming traffic. This point obtains in a lesser degree today in the case of signals given with the whip to following traffic by the driver of, say, a two-horse van.

Again, it is the universal practice for a man when leading on foot a horse to do so with the right hand. Where the rule of the road is to keep to the right it is obviously dangerous to him. In this case he has to walk nearer to the middle of the road than his animal which, if restive, would very likely tend to push him still farther into the way of fast-traveling traffic. The contrary is the result under the English custom.

As to motor cars, it is, I believe, the general impression that it is easier to deflect to the left than to the right. If this is so safety needs no further argument.

So far as I can see there is only one argument in favor of the "keep to the right" rule. I admit, however, that it has cogency. It is that foot passengers keep to the right on the sidewalk. Under the "keep to the left" rule of the road when they step off the path they do so with their backs to the stream of traffic, and the danger for them, therefore, is greater. The question is then, which of the two methods has the greater recommendation. It is pardonable perhaps that I should allow this to the English practice.

MAJOR C. WARD JACKSON.

House of Commons, London.

[*The suggestion that an automobile turns more easily to the left is a new one so far as we are concerned. It would seem to us that the turn is easier when the driver is on the same side with passing traffic, with the curb or edge of the road on the other side of the car, just as in straight driving. We should think that so far as the motor is concerned, preference for the right-hand or the left-hand rule of the road is entirely a matter of right-hand or left-hand drive. Certainly our rule of the road is the reason for the left-hand drive in such a preponderance of American cars. This makes the matter adjustable, so far as the motorist is concerned.*—THE EDITOR.]

## Specimens for Exchange

To the Editor of the SCIENTIFIC AMERICAN:

We are members of the Natural History Society of our school and we should like to begin an exchange of specimens with some of your American readers. Several other members of this society would probably also like to exchange specimens from their various geological, entomological, ornothological or botanical collections.

If any of your readers who wish to exchange specimens will write to us at the below-mentioned address we will do our best for them.

Ackworth School, Ackworth, No. Pontefract Yorks, England.

W. R. SANDY,
W. S. LEAN.

## Motor Trucks and Country Bridges

To the Editor of the SCIENTIFIC AMERICAN:

In regard to your editorial under the above title: We have been getting excellent results on country bridges by changing our flooring from right angles to transportation, to parallel, and find it cuts down impact and vibration to a considerable degree.

It is also more economical as to replacements, as only the tread planks need renewal.

Lenora, Kan. J. C. BECKER.

## Edison and Life

To the Editor of the SCIENTIFIC AMERICAN:

I have read in your number of October 30th the interview with Mr. Edison concerning his theory of the nature of life. It seems to me extraordinary that this great inventor and practical scientist could have indulged in such a futile and inconclusive process of reasoning. The problem is to account for conscious subjectivity (or personality) in man and to discover whether this conscious subjectivity persists or disappears. Mr. Edison's theory is that personality is merely the resultant of the joint action of myriads of hypothetical entities living in a community which disbands at the death of the organism they inhabit. These entities he endows (anthropomorphically) with human intelligence. Speaking of the restoration of the skin upon a burned thumb he says, "I firmly believe that the life entities rebuild that thumb with consummate care, drawing upon their remarkable memory for all details." In other words, he substitutes for the mystery of conscious subjectivity in man the equally insoluble mystery of conscious subjectivity in a theoretical being of infinitesimal dimensions. If Herbert Spencer were alive he would characterize this reasoning as "merely placing the problem a step further back."

The enigma of mind remains equally beyond the reach of our knowledge whether we think of it as appearing in man or in the far-fetched entities, which Mr. Edison supposes man to be composed of. Furthermore, it is of interest to inquire why, if the faculties of mind, as we know them in ourselves, are the ephemeral result of the community action of entities, these same faculties, as exhibited by the entities in the intelligent rebuilding of injured thumbs, should be immortal. Why are not the entities themselves mere communities of still more infinitesimal entities?

This incursion of our world-famous inventor into the philosophical field does not seem to have been felicitous.

**Measuring a year's crop of snow in the California and Nevada mountains**

# Surveying America's Snows

## How California and Nevada Forecast the Amount of Power and Water That They May Expect Each Year

By James Anderson

ONCE more the eyes of the world, or at least every section of the globe where heavy snowfalls are of periodical occurrence, are focused on the United States. For this country has taken one more step forward in the world of science. Realizing that probably the greatest stock of potential energy, greater perhaps than that of water, the snow in the mountains, was unmeasured and its moods not fully understood, the State of California has joined hands with Nevada and the United States Weather Bureau in a survey of the snow in the Sierra Nevada Mountains in an effort to forecast the stream flow in the two States. The progress of the movement will no doubt be a vital factor in the industrial and agricultural pursuits of those sections of the world where heavy winter snowfalls are of annual occurrence.

When these surveys have become general and results have been carefully tabulated and regularly published it will be possible for farmers to determine accurately in the early spring the exact amount of water they can depend upon during the summer months or growing season for irrigation purposes and they can thus plant their crops accordingly. Manufacturers depending upon water power to run their plants will also be able to figure how they will come out in this respect even during the dryest seasons.

Although pastiming in the white mantle of nature is considered primarily a winter sport, the business of snow surveying is indulged in during the spring and early summer months. A comprehensive plan has been developed to study the mountains of California and Nevada as one great system. Two quadrangles have already been formed consisting of the Central Sierra and Northern Nevada watersheds. Two more will soon be formed, consisting of the Southern Sierra and Northern Sierra Quadrangles. How large these quadrangles are can be estimated from the fact that the Central Sierra Quadrangle includes the Yuba, American, Mokelumne, Stanislaus, and Tuolumne Basins on the west slope with the Tahoe, Carson, and Walker Basins on the east.

Eastern and western outposts to the crest stations will be established in every basin to determine oscillation in the snow cover. The monthly increase of the snow cover and the probable demands will be determined by surveys at key stations each month throughout the winter, while a comprehensive survey will be made in April and May to determine the summer flow.

The origin of this new industry is peculiarly interesting. During the winter months both the faculty and student body of the University of Nevada for years derived a great deal of pleasure and sport from trips to the highest snow-clad peaks of the surrounding mountains. Dr. J. E. Church, Jr., was regarded as one of the leaders in these pleasure excursions. After innumerable trips into the winter Sierra his feeling changed from one of pleasure hunting to business. He remained longer than usual and started to investigate the snowfalls from a practical point of view.

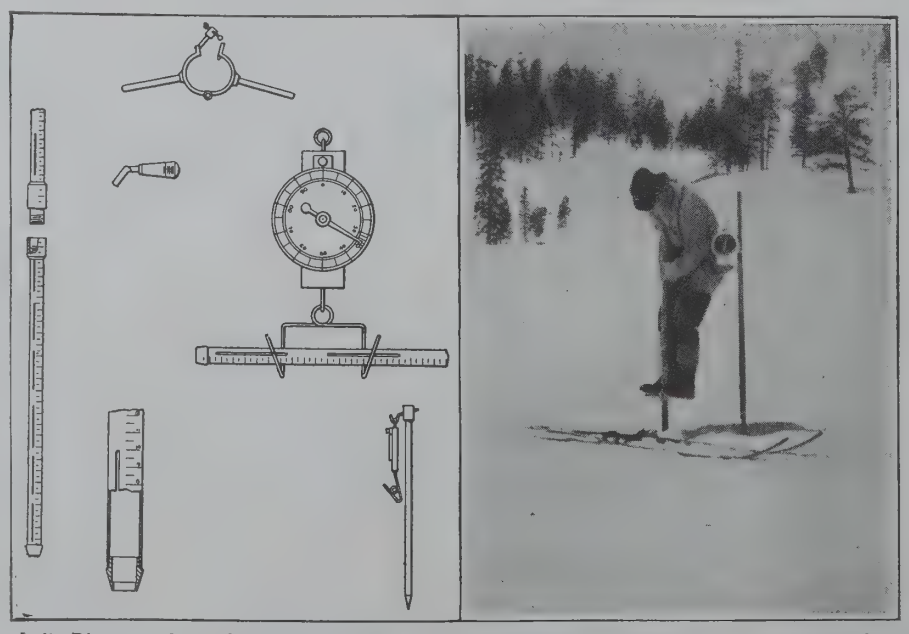
That was about ten years ago. He became so interested in his observations that on the summit of Mount Rose, which overlooks Lake Tahoe, and rises to a height of 10,800 feet above sea level, he established a mountain observatory and, in comradeship with a constantly changing series of faculty and student enthusiasts as the years passed by, gradually developed the method of snow surveying. This, in its simplest form, consists in determining the seasonal percentage of the winter snow cover of the high mountains and using the percentage thus gained as closely representative of the summer flow of the streams which are fed from this source of snow supply.

"Ten years have been spent at Mount Rose Observatory in developing our work," said Dr. Church in telling of this new science of snow surveying, "and many years more will be necessary under the coöperative plan to bring it to fullest service of the farmer and the manufacturer. The ultimate goal is to develop a despatchership of streams similar to the despatchership of trains on the great railway systems.

"After my years of observation I have found these surveys to be unfailing in their determinations of stream flow, allowing for a maximum of a twenty-five per cent shrinkage at times, which may be accounted for by lack of precipitation in April and May. Rain or snow falling in these months is conserved to a better advantage than that falling in June or July, for the obvious reason that during the latter months the moisture soaks into the soil of the mountains, and does not run off into the mountain streams. Shrinkage is one of the most vital problems related to stream forecasting.

"That there is a general relationship between the snow cover and the flow of the streams has long been known and attempts to correlate the two have long been made. Earliest, because of its simplicity, was the method of accumulated snow fall by which the depth of the snow was measured storm by storm. But the density of the newly fallen snow varied so greatly that even the average of a large number of snow falls occasionally caused seasonal distortions as high as thirty-five per cent between the estimate and the run-off."

Dr. Church then explained that the "percentage method" merely involves the searching out of representative areas in the high mountains where the snow lies level and unmelted from autumn to spring. Because of this fact late spring or early June is considered the best time of the year to do the work of surveying. Courses sufficiently long are laid out to assure an accurate average of the water content of the snow. The average of the annual measurements over a period of years is the standard from which are computed the seasonal percentages. The normal flow of the stream draining the basin is determined in a like manner from the stream measurements made by the U. S. Geological survey.



*Left:* Diagram of sampler and the dial that enables the surveyor to estimate the water equivalent of the snow it brings up. *Right:* Driving the sampler into a deep snow deposit

**Finding how much water will run out of a big basin from the snow that lies therein**

The instrument used in the surveys is a thin, steel tube so small in diameter that it can be extended by additional sections to a length of 20 feet without becoming too heavy to drive. A milled cutter and special adjustable wrench on which the surveyor can stand and thus become a human pile driver makes it possible to drive through snow however hard and deep. This sampler is now being used by the Swiss Glacier Commission to penetrate the upper layers of the Alpine glaciers and unlock the secrets of glacial growth. An aluminum spring balance with adjustable index, to eliminate the weight of the sampler, makes possible the immediate determination of the water content of the snow without computation.

The chief disturbing factor between the equilibrium of the estimates and the

## A Unit System of Freight Transportation

**By Charles N. Winter**

THE economic efficiency of the United States and of the world at large is being seriously hampered by the inadequacy of the transportation systems upon which the world's commerce depends. This is particularly true of the railroads of the United States but applies to the waterways as well. In both these branches of transportation, the terminal facilities are unequal to the constantly growing demands made upon them. The methods now employed to handle freight are for the most part so antiquated and slow that it is practically impossible to handle the business offered to them. A step toward relieving the situation appears to have been made by the use of the freight unit shown in the accompanying illustrations.

This unit consists of a rectangular container made of steel plate strongly reinforced with angle-irons and designed to be interchangeable between a truck, a railroad flat car, or a boat, thus linking the manufacturing plant with either rail or water transport, by means of the motor truck. It speeds up the handling of freight by loading it into a 2½-ton or a 10-ton container and moving the container with the contents undisturbed instead of handling a large number of smaller packages. This not only facilitates the transfer of merchandise, but as the container is both weather-proof and thief-proof, the loss so frequently incurred from those causes is eliminated. In addition, the manner in which the freight is packed in the container and the fact that the freight itself is handled only at the shipping point and at its destination, will prevent much of the damage occurring in train movement when goods are loaded loosely in a car or when less than carload shipments are transferred at junction points.

The complete equipment includes a specially constructed flat car which, however, differs from those now in use on the railroads of the United States only in providing a means of clamping the containers fast to the platform of the car. Engineering estimates place the cost of equipping a car with five 10-ton units at $1,000. The flat car may be constructed for the same cost as those in general use or an ordinary flat car may be altered to carry the containers at an approximate cost of $250.

This system was adopted by the United States Railroad Administration after an extended investigation of freight handling methods both in the United States and abroad. It was placed in operation and used successfully in inter-water-rail transport on the Warrior River in the New Orleans district for handling war supplies.

The containers used in that service are of 10-ton capacity and have side doors through which package freight is loaded or unloaded. Steel cables attached to lugs at the top corners of the container provide a means of lifting it from a truck and placing it on car or boat. To do this a crane or derrick or similar equipment is required. Such devices usually are available at manufacturing plants and in the larger freight yards and terminals but when, at small freight stations, such apparatus is not available the containers may be placed on a car and loaded in the sme way as an ordinary box car.

Another type of container is used for handling loose bulk material such as is generally carried in a gondola car. This type is constructed with top doors—and sometimes with a drop bottom—and can be loaded by hand or with material handling devices such as automatic buckets. This container is lifted by links attached to a spreader bar and engaging in slotted trunnions on the sides of the container. When the loaded container is in the desired position, the link latch is withdrawn and the container overturned, discharging the load or, when of the drop bottom design, the load is discharged through the bottom.

Other designs of this unit provide for refrigerator service; for the shipment of live stock; and tanks for liquid shipments. This system therefore is extremely flexible and any or all of the various classes of freight may be transported in small quantities on the same car with many of the advantages of carload shipments and none of the disadvantages of the present method of shipping less-than-carload freight.

Conservative estimates based on the performance of the new freight unit in government service indicate that the handling of freight may be greatly expedited by its use and that the cost of handling will be reduced to one-third or one-fourth of the cost of the older methods of handling the individual packages.

The advantages of this system are that it will unify the highways, the waterways and the railways; deliver freight from origin to destination without rehandling regardless of distance or number of transfers; protect freight from theft, contamination, or fire and water; increase the transportation mileage of motor truck equipment; permit the loading of freight before the arrival of the car; unload and release cars in from 1 to 2 hours instead of 12 to 24 hours, thus increasing freight car mileage; and convert a flat car into a box car or a gondola car as may be desired. Because of the great decrease in the time required for loading or unloading it will increase the capacity of terminals without any outlay except for the lifting apparatus. Its use should reduce joint river-and-rail rates, speed up river traffic, and relieve congestion at terminals.

**The St. Paul bridge that runs like an elevator and is operated like a street car**

## Applying Elevator Principles to the Railroad Bridge

**By Hjalmer Lindquist**

INSTEAD of swinging on a pivot or opening like a jackknife, a Minneapolis railroad bridge lifts itself up after the fashion of an elevator. The mobile section between the two towers is 96 feet long; its weight is 450 tons. This great mass is counterbalanced by two huge concrete weights, one at each end of the elevating section, together weighing nearly as much as the bridge section itself, so that two electric motors in the house on top can lift it with ease to the height of 55 feet in order to pass river traffic.

The concrete weights that slide up and down in the towers are each connected to the end of the movable section by 16 two-inch cables, eight on each side of the weights, passing over the large pulleys at the top of the steel towers. The signal control and lifting machinery is in the house on top of the bridge.

When a boat signals its desire to go under the bridge, the watchman turns on the electric current that operates the signal system and manipulates two levers controlling semaphores at either end of the bridge in order to warn all trains to stop. He must then wait a full minute before he can unlock the bridge section from its two ends. This is accomplished by pushing a lever. Switches are simultaneously operated as to derail any train attempting to pass the danger signals.

With the trains blocked at both ends of the bridge, the operator now unlocks the section, steps to the control drum, and gradually applies the current which operates the lifting motors. This control drum has much in common with the street car controller; in fact, the entire operation of lifting the bridge follows the manner of running an electric car. To raise the bridge the current is turned on and increased gradually. Going down, the reverse lever is first pushed into position and the power is gradually applied.

Signal lights on both sides of the bridge at night indicate to boat pilots when it is safe to pass under the raised bridge. A ball signal on top of the station, which may be raised and lowered, is used in daytime.

On the wall and rising from the floor of the control house are indicators that give the operator all the information he needs, making it unnecessary for him to look out the windows. Indicators tell the bridge operator if there are trains standing on the approaches and on what tracks they happen to be. A machine rising from the floor tells him to the fraction of an inch just how high his section is from its bottom or resting position. The operator cannot see at night how things are on the outside and no chances are taken of his making a mistake through the day.

A worm screw, about two feet long, is timed to trip a lever and break the circuit at both ends when the bridge section has come within three feet of the top or bottom of its travel. This device also makes for safety by stopping this machinery; it warns the operator to look at his indicator. To start it again he has only to press a button on the drum.

The average time to bring the bridge to the top of its 55-foot way is one minute; it can be done in half that time. The downward speed is the same.

# Wanted: An Inexpensive House

## A Review of the Building Situation and a Few Timely Suggestions

By Harry A. Mount

THE present housing situation, viewed through a pair of horn-rimmed spectacles over a mahogany committee table, presents an unusually knotty problem. But viewed through the eyes of the man who, with his household goods in storage and his family in a hotel, watches his savings account melt away while he searches frantically for a "permanent location," the whole matter is taken out of the category of problems and heads the list of pressing necessities.

Many thousands of persons have viewed the housing problem from this angle in the past three years. Those who have not solved it in a makeshift way have sooner or later come to consider how they might own their homes, with a limited cash outlay.

Everywhere in the building industry just now one is impressed with the fact that this a poor time to build a home. The cost of materials and labor is such that experienced builders have almost ceased operations. Such building as is going on is under the press of necessity or is being done by realty speculators who hope to dispose of their houses at a large profit before the housing shortage can be relieved.

Now as a result of this cessation of building there is already noticeable a considerable downward trend in the price of building materials. Men who have studied the situation emphasize the fact that thousands of persons who have bought homes of their own on the partial payment plan have taken upon themselves a bigger financial burden than they will be able to carry on a falling market. One large manufacturer of ready-cut houses made the frank prediction to the writer that within two years hundreds of these houses built for speculation would be upon the market at very reasonable prices.

A man need not go deeply into present building conditions to discover that it it is neither possible nor desirable to engage in ordinary building operations at this time on a moderate income. But as to the desirability of building now, the foregoing fact can be overlooked when building is a necessity. Then, too, there are ways to economize in building a small residence to bring the cost within average means, and that is the subject of the following lines.

First of all, let us admit that if the home-builder has a little mechanical ability and is able to wield a hammer and saw, the problem is much simpler. Now then, we must begin by acquiring a bit of land—a lot, if you please.

Once the lot is clear of indebtedness a building loan can usually be negotiated. Building and loan associations are organized for this purpose. Some of them, however loan only to bonafide home builders and refuse loans to realty speculators. Such firms are likely to treat the builder with far greater consideration than might be had elsewhere. One New York concern employs investigators who, when payments on a loan begin to fall in arrears, discover whether or not there is a real reason, and whenever possible arrangements are made to tide the borrower over a temporary financial stringency. Thousands of other firms are just as considerate in making loans to home-builders.

One of the first considerations in laying plans for a small home should be the local building restrictions. When possible a copy of the local building code should be secured and carefully studied. If much of the work is to be done by the builder himself a preliminary study of the code may save him costly rebuilding and a possible fine later, should a building inspector suddenly appear on the scene.

It is far safer, when one intends to do part of the work, to secure the advice and assistance of an experienced carpenter from the very beginning. The whole job will proceed faster and at less expense under his direction.

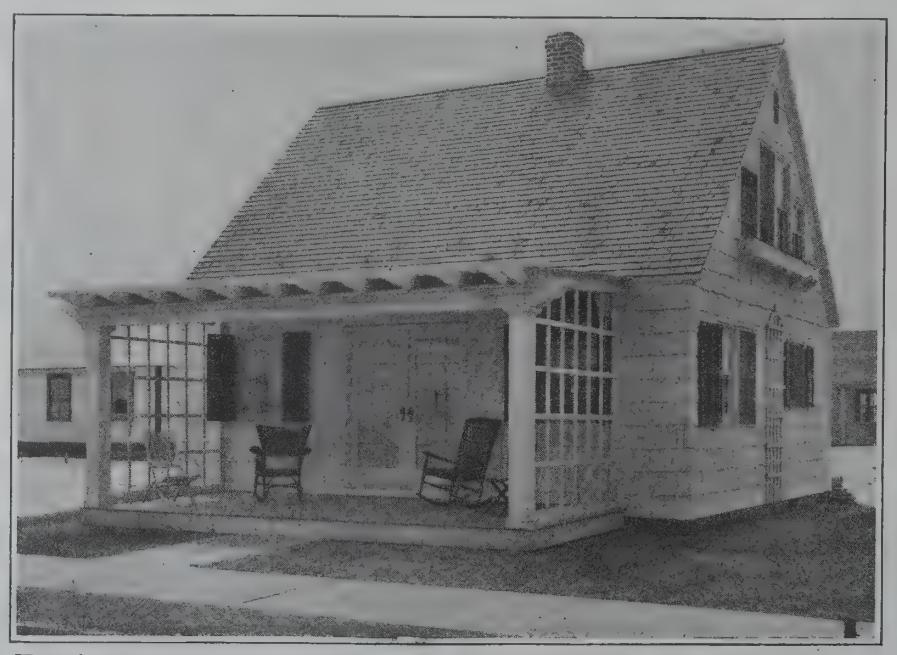
Another precaution to be observed is this: do not buy your lumber and materials at the nearest lumberyard without asking prices elsewhere. At times there is a sharp difference in prices even at nearby lumberyards, especially under present abnormal conditions.

Under very favorable conditions, and provided a part of the labor is done by the builder, a three or four-room cottage can be built for as little as $1,500. This figure contemplates a very small house of rather severe architecture, but well built and sealed so that it would be suitable for winter use. Let us have no illusion regarding a $1,500 house.

It would have no cellar; it would be roofed with composition shingles, and plaster board or wall board would be used on the walls. On each of these items there is a great saving in labor over standard practise.

If one has sufficient spare time, or can spend the days of one's vacation solving the housing problem for once and all, even the services of the carpenter can safely be dispensed with if one of the various types of fabricated houses now on the market is purchased. The lumber for these houses is delivered from the factory ready cut. Complete instructions accompany the materials and any man who can drive a nail straight can put them together. In some types the lumber comes made up into sections and these have simply to be nailed or bolted together.

*IT was altogether to be expected that the Editors of the* SCIENTIFIC AMERICAN *should be appealed to for aid with regard to the housing shortage. Here and there large plant executives and municipal authorities have asked for guidance in the matter of building homes for workers whose means called for inexpensive houses. And these appeals were answered by mail—answered individually and personally so as to take care of the peculiar requirements of each. All of which prompted us to formulate an interesting little problem in building, namely: Can a house be built for $1,000, and how? Mr. Mount, one of our regular correspondents, has attempted to solve the problem in the accompanying account. He sets the lowest limit at $1,500 for a very modest house, and gives a number of suggestions for inexpensive building operations. But our problem remains unsolved! Can any of our readers solve the $1,000-house problem?*—THE EDITOR.



**Here is a typical ready-cut house which is assembled by means of bolts in a minimum of time. The cost is about $6,000.**

The manufacturer of ready-cut houses has already taken care of the details such as design, compliance with building codes, selection of proper materials, etc. Because these houses are produced in quantity in a well equipped factory, the labor cost on the work already done when the lumber is delivered is obviously considerably less than if it were done on the job. The services of the architect who has designed such a house would be beyond the reach of the average home-builder; and the assurance that the architecture is correct is most comforting, even though the house be a modest one.

Buildings of the ready-cut type range from lightly-built summer houses of three or four rooms to eight- or nine-room houses, running in price from a few hundred dollars to $15,000 or more. The home shown in the accompanying photograph is the most popular model of a highly popular line of fabricated houses. It contains five rooms, ideally arranged for the small family. The cost, complete with foundation, plumbing and lighting equipment, ready for occupancy, is about $6,000. The cost of the bare house is $4,500 at the factory.

In this type of house, the material is made up into three-foot sections at the factory and the whole house is put together without nails—excepting in the walls—bolts being used throughout. Even the shingles are put on at the factory; it is only necessary to slip under a few lap shingles after the sections are in place, to complete the exterior. The idea must not be gained, however, that the construction is flimsy. On the other hand the finished house is of extraordinarily sturdy construction and will pass the most rigid building inspection. The walls inside are finished with plaster board and the house is said to be very cozy for winter use. The factory equipment for the house includes such details as hardware and bricks for the fireplace and flue.

Although the house has five spacious rooms, it occupies only 768 square feet of ground. From the front porch we step directly into the combination living and dining room, through double French casement doors. This room extends across the entire front of the house and a large fireplace in the center adds to its coziness.

In the rear of the ground floor are the kitchen, bath, a bedroom and the stairway to the upper floor. Above we find two cheerful bedrooms. The upper rooms are so constructed that very little of the roof touches them, giving good insulation from outside temperatures. The waste space under the roof is utilized in providing an abundance of closet space.

There is little hope of escaping high costs by the use of material other than lumber. Stone, brick, or cement construction, even though materials may be plentiful and at hand, require expert labor and the final costs are usually much higher than those for lumber. Certain types of molded cement construction, however, compare favorably with wood in cost. One of the most successful of these utilizes a double wall construction, with a dead air space between so that the house is suitable for use in climates where extreme temperatures are encountered. The walls are built by the use of a single mold, about three feet long and a foot deep. This consists of four steel plates held parallel by steel braces at the top. The plates are adjustable so that thickness of the walls and air space can be varied at will.

Concrete is mixed with only a small amount of water and is then tamped into the mold, directly on top of the foundation. Without waiting for the concrete to set, the mold is moved along the wall and another section tamped in. When a complete layer of the wall is thus built up, another tier is begun on top of it and the process continues round and round until the house is finished. The interior walls are of a single thickness of concrete and the whole construction is locked firmly together by the use of special tie-rods which are molded into the concrete.

The windows and doors in this kind of construction are set in place and the walls built around them. A stucco finish is usually applied to the outside and the plaster is applied direct to the inside walls. Cleats, to which the rafters are nailed, are built into the walls.

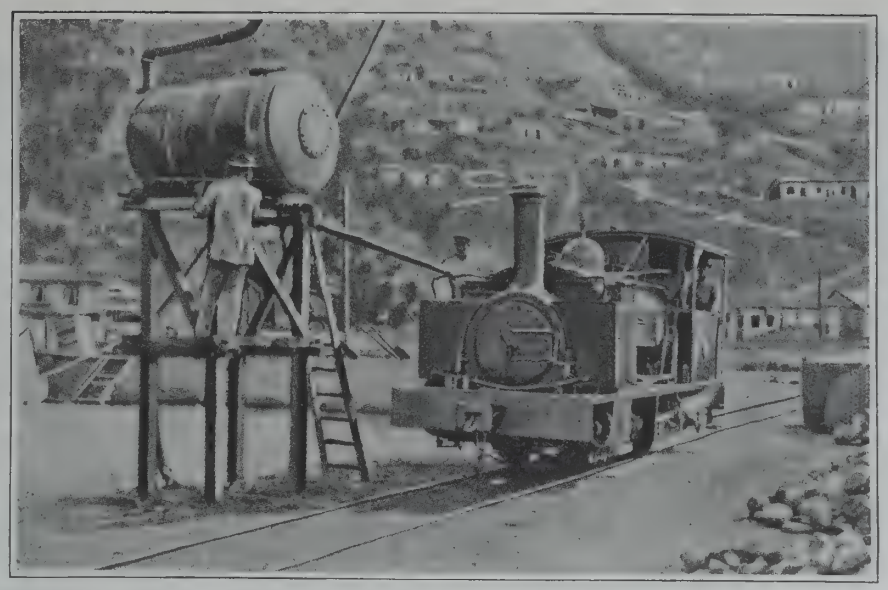
This concrete construction depends largely for success upon good workmanship, and the company which controls the patents sells the necessary apparatus

(*Continued on page 603*)

## Venezuela's Mountain-Climbing Oil-Burning Locomotives

**By Harry Chapin Plummer**

OIL-BURNING locomotives have lately supplanted coal engines on two of the steepest of trans-mountain railways in the Republic of Venezuela. The Minister of Public Works, Dr. Luis Vélez, reporting upon the success of the experiments with oil-burners, discloses comparative figures covering the running cost of trains over the 22.36-mile line on a 3.75 per cent grade and proves a saving of not less than sixty per cent in cost per train mile in favor of the new principle. The railway upon which the official experiments were conducted is the British-owned road operating between La Guaira, the chief seaport of Venezuela, and Caracas, the capital city. Hitherto the line has been operated at an annual cost per train kilometer (0.62137 miles) of 6.31 Bolivars ($1.26).



**Refilling the tank of a Venezuelan oil-burning locomotive employed over the mountain railroads**

The latest economy to be effected in the management and operation of the Caracas-La Guaira Railway bids fair to further its reputation for earning capacity. Within a quarter of a century the ratio (representing net revenue) of operating expenses to income was widened from Bs 1,972,282.46 ($385,656.49.1), the disbursement total for 1893, as against a gross revenue for that year of Bs 3,641,565.89 ($728,313.19.4), to Bs 965,232 ($193,044.20), the disbursement total for 1918, as against a gross revenue for that year of Bs 1,782,375 ($356,475).

Yet another of several British railways in the country, which represent an aggregate investment of Bs 89,485.500 ($17,897,200), has adopted the oil-burner.

The total railroad mileage of Venezuela today is 1,039 kilometers (645.37 miles). Three of the roads are State-owned, two are privately operated by Venezuelan companies and seven are under the control of English, German and French interests.

Minister Vélez, in reporting to the Venezuelan Congress upon the Caracas-La Guaira Railway observed:

"An instance of progress which we consider very important from the practical and economic point of view, introduced recently in the operation of some of our railways, is the use of national crude petroleum as a combustible for the locomotion of the trains. This practice has for us actually a double value—that of the traffic in a national product and that of our market coming under the influence of the universal crisis growing out of the war in the branch of combustibles. Five companies have commenced to introduce this improvement or to equip their respective hauling apparatus for the change in fuel."

Citing a test made on the heavy grade of the ascent from La Guaira to Caracas in two trips over the 22.36-mile run, in one feeding the locomotive with Cardiff coal bricks and in the other with crude petroleum, the comparative results are set forth as follows:

| | Trip in which Cardiff coal was used | Trip in which crude petroleum was used |
|---|---|---|
| Dead weight of train | 50 tons | 63 tons |
| Total consumption of combustible on each trip | 850 kgs. coal | 660 kgs. pet. |
| Consumption rate per ton and per kilometer | 0.47 " " | 0.29 " " |

"In order to make clearer our comparison," the report states, "suppose the two trains had been of equal weight, of fifty tons each, in that case the combustibles expended would have been, proportionally:

In the case of the coal, 850 kilograms
In the case of the crude petroleum, 524 kilograms

and taking into account that the prices which these combustibles have cost the railway company have been, in the port of La Guaira:

1 ton of Cardiff coal briquets Bs 124 ($24.80)
1 ton of crude petroleum.....Bs 74 ($14.80)

results in showing the cost of the necessary fuel in each trip to have been:

Employing Cardiff coal..Bs 106.75 ($21.35)
Employing crude petroleum Bs 38.78 ($7.75.3)

that is to say, that the use of crude petroleum develops an economy of more than sixty per cent—a very material economy, to be sure.

"From this result it is not difficult to present the following figures, experimentally obtained, as to the comparative properties of the two combustibles used in very thorough trials:

Copyright, Kadel & Herbert

**Side view of the new variable-wing plane, showing the three members of the top wing almost entirely overlapped or closed**

## An Airplane with Variable Wing Surface Area

**By Alfred Longville**

THE idea of varying the area of the airplane wing while in flight is by no means new. As early as 1910 certain French designers conceived of airplane wings with airfoils that could be rolled up much after the fashion of the sails aboard a sail boat. The idea has always been to employ a wide expanse of wing surface while climbing to the proper altitude, and then reduce the wing surface in order to increase the horizontal speed. But the apparently successful execution of this idea is a matter of current event, and then only on an experimental scale.

No lesser aeronautical minds than Gastambide, Levavasseur, and Latham, the latter a cousin of the famous aviator of that name who was killed in Africa while on a hunting expedition, have evolved an airplane with wings of variable area. The new airplane, which is shown in two of the accompanying illustrations, is a one and one-half biplane, so to speak, for the reason that the lower wing is barely half as large as the top one. The machine is equipped with a 250-horse-power engine, driving a single tractor screw. The body is exceptionally thick yet properly streamlined to obtain the best aerodynamic results.

The novel feature of the airplane is the top wing, which, it will be noted by studying the accompanying illustrations, is the variable member. It consists of three sections, two of which, the top and the bottom one, slide more or less over and under the middle section which remains stationary. The narrowest width of the plane closed is 1 meter 60 centimeters (63 inches), while fully extended the plane is 3 meters 28 centimeters, (129 inches). The speed is given as 60 kilometers (37 miles) per hour, with full spread to 200 kilometers (124 miles) per hour, with the wing entirely closed, or a ratio of better than 1 to 3. The wing area is given as 52 square meters with wing fully extended, and 32 square meters with wing entirely closed.

The aviator Grandjean recently piloted the new machine at the flying field at Etampes, France, with excellent results, proving the practicability of the variable wing feature. For military purposes the machine has an immediate and invaluable use, since it can be slowed down for observation and photographing purposes, and speeded up at other times. For sport and commercial purposes, too, this variable speed feature is of prime imporance, since it makes for safer landings. All in all, the new airplane points the way to a new and safer era in aviation.

## Paper from Veneer Waste

IN the wood waste from veneer factories the U. S. Forest Products Laboratory sees considerable raw material suitable for the manufacture of high grades of paper. The cores of many kinds of veneer logs, now used in a large part for fuel, would make excellent pulpwood. In addition, a large part of the clippings could be turned into pulp stock with profit.

Among the veneer woods whose waste has paper-making possibilities are red gum, yellow poplar, cottonwood, birch, tupelo, basswood, and beech. Many veneer factories cutting these species are already within shipping distance of pulp mills. In certain other cases veneer factories are so grouped that they might furnish pulpwood enough to warrant the erection of a centrally-located mill. Other economic factors being favorable, such a mill could profitably operate on a daily supply of veneer waste equivalent to 50 cords of ordinary pulpwood.

# Music from Glass

## Franklin's "Harmonica" and Other Instruments of the Same Class

By J. F. Springer

THE idea of getting musical sounds from drinking glasses or glass basins is at least as old as the middle of the seventeenth century. The finger would be moistened and the hollow glass vessels set into vibration by applying the finger thus prepared. Thus, in an old book printed at Nuremberg, directions were given how pleasing musical tones could be produced. Eight glasses of similar shape, and presumably equal size as well, are taken. Then, a spoonful of wine is put into the first, two spoonfuls into the second, and so on. Eight persons, each with wine-moistened fingers, are now to pass them over the several brims. It is said that there will be heard "a very merry wine-music, that the very ears will tingle." We have here what is apparently an inexact description of how to prepare a complete scale together with the octave of the key-note. Those who try it will doubtless find that the proper intervals from note to note are not so easily got as the description seems to indicate. Naturally, the wine will be no better than water in the various vessels. It was also suggested, in the same account, that a lesser number of glasses might be used and the arrangement be made "by order of intervals of thirds, fifths, and octaves, and, according to the size of the glasses, augment or diminish the wine."

However, from this beginning, the famous *glass harmonica* may have been evolved, although Benjamin Franklin is nevertheless to be credited with its invention. But he himself attributes the first thought of playing tunes upon drinking glasses to a Mr. Puckeridge, a gentleman from Ireland. According to Franklin, Puckeridge actually grouped together a lot of glasses of different sizes and tuned them by putting in more or less water, as the case demanded. The instrument together with its maker and the house itself was unfortunately destroyed by fire. But a Mr. E. Delaval, a member of the Royal Society, imitated and apparently improved upon the earlier instrument. He gave particular attention to the form of the glass. This was the first instrument seen or heard by Franklin. He was delighted with the sweetness of the musical tones.

In Franklin's instrument, the seven notes corresponding to the natural scale were painted red, orange, yellow, green, blue, indigo, purple, and then the same succession of colors was given to the next octave. By this device, octaves were always of the same color. The five glasses representing the interspersed intermediate tones, which we usually assign on the piano to the black keys, he colored white. The player seated himself before the middle of the set, just as he would in seating himself at a piano or organ, and turned the glasses by a mechanical device operated by the foot. Every now and then they were to be freshly wetted with a sponge and clean water. "The fingers should be first a little soaked in water, and quite free from greasiness; a little fine chalk upon them is sometimes useful to make them catch the glass and bring out the tone more readily." Both hands could be employed, so that some attempt at harmony was possible. "Observe that the tones are best drawn out when the glasses turn *from* the end of the finger, not when they turn *to* them." Franklin's improved form of instrument dates from about 1762. There is, in the *Vicar of Wakefield*, an apparent reference to the novel instrument under the name of "musical glasses."

The instrument was used in exhibitions in France, Germany and Austria. The noted Italian poet, Metastasio, heard the instrument in Vienna and became enthusiastic. A certain Ferdinand Pohl, an artisan living in a Bohemian town, heard of the famous instrument, but appears to have had few details. He knew, however, that glass was the fundamental material. With this in mind, he thought that the glass bells used to protect clocks from dust could be utilized as means for producing the notes. His first instrument was at last finished, after much effort and neglect of ordinary duties, and he opened the door of his work-room to call his wife. Just then, a draft slammed the door with the result that a picture fell and ruined the instrument. Nevertheless, he went to work again, and this time with more lasting success. The Pohl form of instrument became celebrated throughout the world.

The glass harmonica has not become a permanent thing. There are probably a number of instruments—

*(Continued on page 604)*

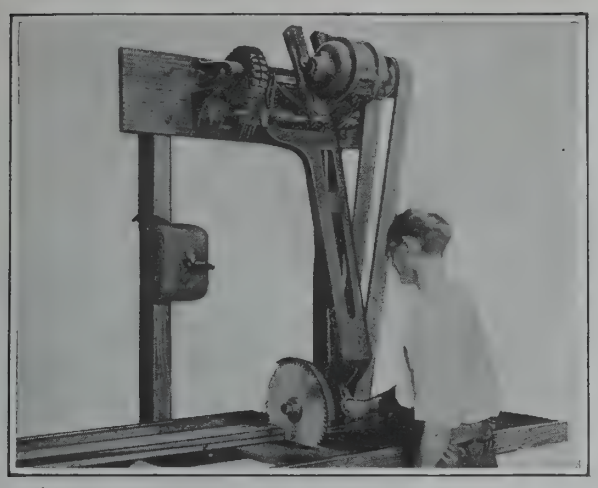
**Some unusual musical instruments of glass**



This swinging saw is so constructed that it cannot swing back and injure the operator

## Swinging the Saw to Cut the Wood

A CINCINNATI manufacturer has lately brought out a new type of swing saw which protects the operator by its new mechanism swinging the saw back automatically and away from the lumber being cut when the handle is released. This allows the operator to remove the cut lumber without the danger of the saw swinging back and cutting his arm or hands. The safety lock attachment keeps the arm from swinging forward unless the handle is pulled by the operator.

The saw is a self-contained unit and may be easily installed by hanging to any convenient wall or column and connecting motor to the nearest electric wires. A switch inserted on the saw frame makes it possible to turn off the current when the saw is not in use without leaving the work in hand.

The safety feature of the saw will make it particularly adaptable to the use of merchandising plant shipping departments where frequent changes of employees might result in serious accidents with the use of machines not equipped with the safety device.

## Paper Pulp in New Zealand

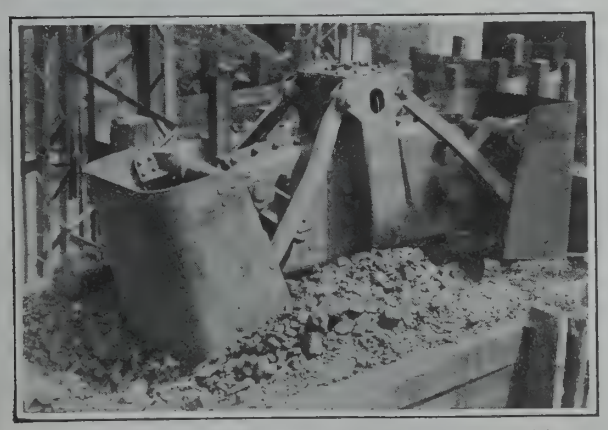
THE New Zealand Government has granted a lease of 30,000 acres of white pine land and also water rights for the generation of electric power to a company which intends to use the pine for paper-making, a purpose for which it is claimed as very suitable. At present all the newspaper used in Australasia comes from either Canada or Scandinavia and the pine has risen from under £20 to £80 a ton in the last few years.

## Enclosed Gears for the Clam-Shell Bucket

THE use of clam-shell buckets in handling bulky materials, such as coal, sand, gravel and cinders, has always been accompanied by expense and serious delays made necessary by the renewal of operating cables and chains. Ordinary clam-shell buckets are so constructed that a large quantity of the material handled comes into contact with the operating parts of the bucket. This results in excessive wear of the operating parts due to the abrasive action of the material.

Such faults have been eliminated by the clam-shell bucket developed recently by a Cleveland manufacturer. All of the working parts of this bucket are enclosed in a tight casing where they are constantly lubricated and where they do not come into contact with the material being handled by the bucket.

The bucket is made of a minimum number of parts which are arranged to facilitate the removal of any part in case of necessary repairs. The accompanying close-up view shows the bucket's simplicity.



A clam-shell bucket in which all the working parts are enclosed and protected

## Using Compressed Air to Reclaim Bolts

A BOLT-RECLAIMING device is the invention of H. U. Prindle of a Pacific coast shipbuilding company. It is destined to hasten the work of preparing bolts that have been once used, for further use. Customarily, this work is done by hand, it being necessary to work the nut off the bolt—generally this necessitates a hammer—and then to clean the threads. Frequently it is necessary to re-thread a bolt, or to make a smaller bolt from it, in order to use it all. The average number of bolts cleaned per day by hand, as against the number with a machine, varies in the proportion 198 to 1,000, over five times the number being accomplished with the machine.

This machine was built of scrap iron and steel. It consists of a receptacle for the nut—the round object in the center of the picture—which revolves in either direction, and a stationary slot for the bolt, to insure its being held straight. This is the slot seen just above the nut-receptacle. To reclaim a bolt, it is slipped in the machine and held by hand, while the receptacle for the nut is worked back and forth rapidly, a short distance at a time. This not only removes the nut, but also cleans the threads without injuring them and increases the efficiency of the nut from three times, as is the case with the hand method, to ten times or more with the machine. Four other similar machines are being built at this shipbuilding plant.

An air-operated bolt reclaiming device which expedites the cleaning of screw threads

## Iron and Steel in Australia

THE Australia output of iron and steel, at present comparatively small, will probably show a marked increase in the near future. The Broken Hill Proprietary Company is enlarging the capacity of its steelworks at Newcastle while the Queensland Government has decided to establish State steel and iron works at Bowen. It is estimated that these will cost between $10,000,000 and $15,000,000 and employ, when in full operation, about 4,000 men. In view of the adverse rate of exchange with the United States an effort will be made to secure the machinery entirely in Great Britain and Australia. While the works are not likely to be completed for three years it is hoped to begin production 12 months after the arrival of the machinery. Railway rails for the State lines will bulk large in the output. A group of Scottish ironmasters is trying to arrange to work the iron deposits at Yampi Sound in Western Australia where there is a hill of exceptionally pure iron ore immediately on the shore of a fine harbor. It is officially estimated that there are 97,000,000 tons of ore of very light purity in sight above water-level while the total quantity is probably much greater. It has been proposed that the melting works should be established in Portuguese Timor, 300 miles from Yampi Sound, where manganese and fluxing materials are available while coal could be obtained from Borneo. It is unlikely, however, that the Australian Government will allow the ore to be exported to Timor and there is an alternative proposal to have the works at Gladstone, in Queensland, where plenty of coal is available close to a good port. There is a rise and fall of tide ranging up to 38 feet at Yampi Sound and if the problem of securing electric energy from the tides could be solved smelting could be done very cheaply on the spot. There is also a probability of a big iron and steel industry being developed at Loraina in the island of Celebes, a port of the Netherlands Indies. This has a field within 18 miles of a port estimated to contain something like 200,000,000 tons of ore yielding 50 per cent of metallic iron, chrome iron, nickel and manganese.

A clothes sprinkler made of aluminum after the fashion of a salt shaker

## The Salt-Shaker Idea as a Clothes Sprinkler

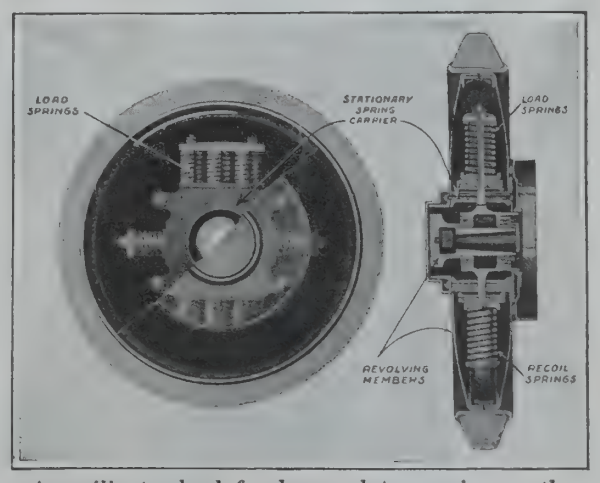
FOR the woman who still insists on doing some of her washing, a Bloomington, Ill., manufacturer of aluminum ware has brought out an aluminum clothes sprinkler. A screw top containing a large number of small needle-point holes affords an even spray of water. One filling of water should be sufficient for the average washing as it will hold a little more than a half pint of water.

## A Resilient Wheel for the Solid-Tired Truck

A NOVEL form of resilient wheel designed for heavy power vehicles, operate on a new principle, has been recently devised. As illustration shows, the wheel is not built on the same principle that most spring wheels are. In the design outlined the wheel is mounted on an axle member and secondary springs surround this axle. A frame on each axle end is permanently positioned and in this there are eight coil springs, three being carried above and three below, while there is one spring on the back and one at the front of this frame. The springs are so placed that there is a certain degree of tension on them which is claimed to make for steadiness of action.

The construction of the resilient wheel is such that the load is carried by the upper springs and the recoil of these members is absorbed by the lower springs. The wheel has two sets of parts, one being stationary at all times, and the other capable of revolving. The rotating series includes the wheel disks, tires, bearing inner races and the wheel driving members. The stationary series comprises the bearing outer race, the spider block springs, spring bolts, spring bridge and spring plates, and these parts always maintain their position because the spring carrying block is keyed to the shaft or shaft housing depending upon the design of the axle. The horizontal front spring is compressed only when the clutch is engaged while the horizontal rear spring is loaded only when the brakes are applied.

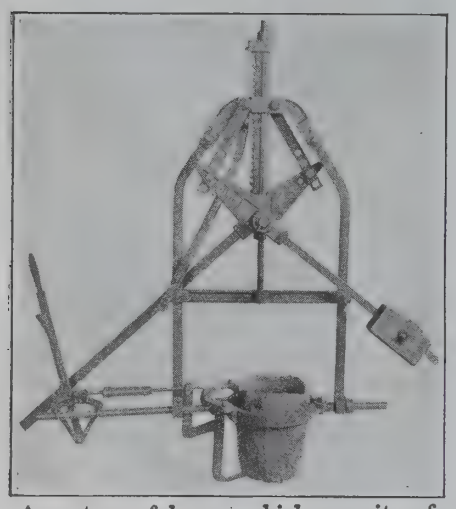
It is stated by the builders of the new wheel that the factor of safety is so large in this design that there is no possibility of the springs breaking as the carrying capacity is 100 per cent greater than the capacity of the main frame supporting springs. By the use of this floating hub construction, it is advanced that great ease of riding is obtained, that the usual form of solid rubber tire is satisfactory under all conditions and that higher speeds are possible without damaging the mechanism, than can be obtained with the usual form of non-resilient wheel.



A resilient wheel for heavy duty service on the largest of present-day motor trucks

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



A system of levers which permits of one man handling a 400-pound ladle

## A One-Man Ladle for the Efficient Foundry

IN the average small foundry where molten metal in small quantities is poured into molds for making light weight castings, it is usually necessary to carry the metal to the molds in small ladles called bull or shank ladles. This involves the liability of spilling the metal causing injury to the workmen or loss of the metal or both.

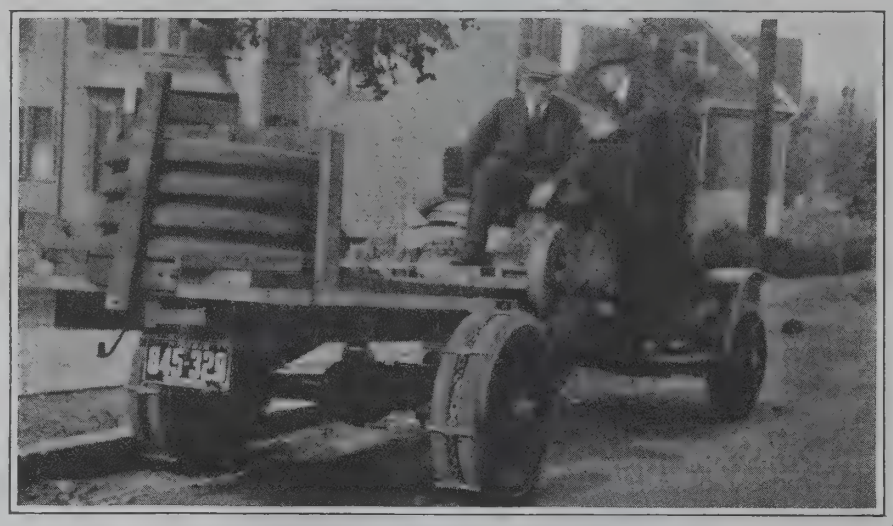
A new device, claimed to overcome these troubles and to represent the latest ideas, has been put in the market by a company of Detroit. The novel feature of the new device is that it is mechanical and is the product of scientific study. In foundries where these machines have been used, it is reported that they have quickly paid for themselves. One man, with this device, can pour almost three times as much as two with the old shank method and in less time, it is claimed. The pouring is more accurate with fewer spills and accidents, and with burns almost eliminated.

By means of a set of adjustable levers and a counterbalance a man gets mechanical advantage great enough to lift over 500 pounds. A ladle of 400 pounds capacity is easily lifted to a height of 18 inches, owing to the leverage.

The details of the mechanism for handling heavy ladles are shown in the accompanying illustration. The operating lever controlling the pouring of the ladle appears at the left, and the counterweight at the right.

## A Non-Skid Grip for the Motor Truck Wheels

IN the non-skid device being manufactured by a Connecticut factory, steel cross bars attached to electrically welded chains is one of the latest improvements for the motor truck using dual tires. The chain slips in between the tires and is locked tight. The steel cross bars overlapping the rubber of the tires are round on the tread of the tire. When coming in contact with sharp objects this round bar displaces the rubber passing over the object without damage to the tire or the bar. It is also claimed that the cross bars eliminate vibration.

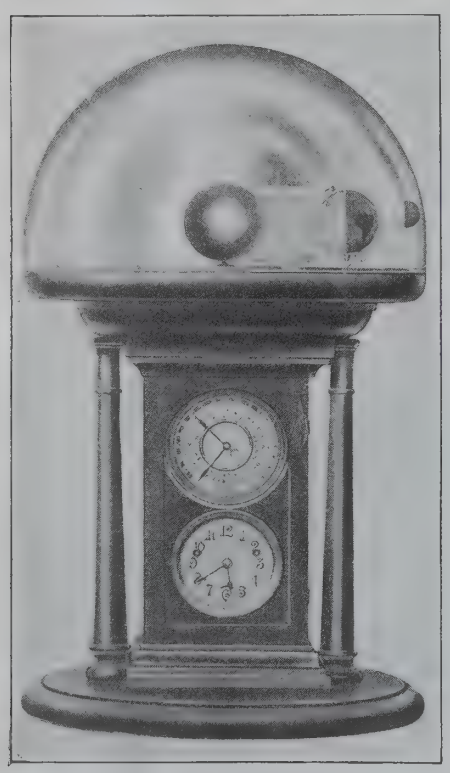


Experimental motor truck fitted with a new type of non-skid arrangement on the rear wheels

## The Life of a Tractor

THE amount of service which a tractor will perform before it must be replaced is obviously an important factor in determining its value for farm work. The United States Department of Agriculture has given serious study to this problem and while it cannot give any official figures that are definite as to the life of the tractor, it gives an average estimate of eight to ten years. Of course, the factors that influence the amount of service rendered by any given machine are, first and foremost, the care that it receives at the hands of the operator, then the quality of the outfit, the kind of work for which it is used, the service rendered by the organization that builds it and the skill with which it is designed and constructed. Nearly all tractors are used under conditions which are extremely severe for any kind of a machine. They travel over rough and uneven ground and work in an almost constant shower of dust and dirt, which is extremely hard on the wearing parts.

White, green, and red lights serve to indicate the speed of the automobile



An astronomical clock which shows the position of sun, earth and moon at a glance

## What Time Is It by the Sun, Earth and Moon?

WHAT is said to be an improved astronomical clock represents the ideas and unrelenting work of an ingenious Chicagoan, Michael Bulka. This clock, which is shown in the accompanying illustration, exemplifies and illustrates the movements of the earth and moon around the sun, with the moon swinging about the earth. These various movements, in concert with the actual happenings, typify the four seasons of the year.

In a glass dome surrounding the clock are three globes representing the sun, earth, and moon. This group shows how the sun illuminates the earth and moon; how the earth revolves around its axis every twenty-four hours, giving us both day and night; how the earth travels around the sun, giving us the four seasons of the year; how the moon revolves around the earth, thus changing its illuminated area; and how the earth and moon together revolve around the sun, giving us the twelve months in the year. The eclipse of the sun and moon, when they occur, are plainly depicted by the mechanism. The globes representing the sun and the moon have been coated with phosphorous preparation which radiates rays of light. The clock has two dials indicating time of the year and of the day.

## Colored Lights to Indicate the Speed of Cars

A SPEED indicator for motor vehicles "to be seen and read by all men" at a glance and that registers speed by the flash of colored lights, is the recent invention of Col. Charles Gore of Los Angeles.

The mechanism is encased in a metal box to be fastened to the front of the radiator. In the box or case are three large *eyes*, white, green and red, respectively. A regular speedometer cable connects the mechanism with the front wheels of the car, and when it begins to move the white light burns automatically.

This continues until the rate of travel passes the limit of the city ordinance, when the green light comes on, showing that the county rate is being used. If the driver exceeds that the red light flashes its signal of danger to all within seeing distance. Since the mechanism cannot be manipulated from within the car, it is impossible for the motorist to falsify his speed.

These lights lock automatically; hence if a driver breaks the city law for only a few minutes the green light will continue to burn after he has slowed down to the white range. By this means a traffic officer or any observer outside the car can tell by a glance what has been the rate of travel. In case of accident the lights burning will be conclusive evidence, registering either for or against him.

One who is an innocent victim of another's speed or a pedestrian's blunder will not be held up unnecessarily, causing vexatious delay, or, as is often the case, accused unjustly and convicted through mistaken or willfully lying witnesses. Likewise the guilty can be promptly dealt with, no time is lost, no confused witnesses summoned to court.

The city and county will also be saved much. Costly prosecution and wasted time are eliminated to the advantage of tax-payers. The immutable evidence of the mechanism means swift justice to all.

## Something New in Hose Clamps

ONCE every so often a photograph has been staged in such an ingenious manner that it tells its own story. Such a photograph, we believe, accompanies these few lines. It depicts a new type of hose clamp at the left, and the old-style hose clamp at the right. The new type, it will be noted, is operated without tool of any kind; it is merely necessary to place the ring about the hose, adjust the ring to fit, and then press home the lever member, as shown. The old-style clamp requires a screw-driver and a pair of pliers, as shown at the right.

Copyright, Keystone View Co.

The new and the old types of hose clamps and how to apply them

## The New Battleship "Indiana"

(*Continued from page 587*)

in together and united in a single structure as shown in our engraving. Although the arrangement looks very odd at first sight, it has the advantage of simplicity, and the even greater advantage that it removes the outflowing gases from the neighborhood of the navigating and fire-control positions that are clustered around the forward mast.

Immediately abaft No. 2 turret is the conning tower, which in these ships is built of enormous weight and strength, with an armor protection that will be proof against heavy shells at fighting ranges. The signal bridge surrounding the chart room and pilot house is extended around the top of the conning tower. A notable feature is the use of very long range-finders, 30 feet or more in length. These pass entirely through the turrets and have only their object glasses projecting on each side of the turrets. They are thus very effectively protected against shell fire. Attention is drawn also to the large number of searchlights provided, there being two on specially-prepared towers on each side of the smokestack, and a cluster of several at the first third of the height of the main mast. The complement of the "Indiana" will be about 1,500 officers and men.

## The World's Greatest Shipping Terminal?

(*Continued from page 590*)

330,000 gallons. The average daily consumption is 1,800,000 gallons.

The water system at Hog Island is sufficient to supply a town of 30,000 people. It is interesting to note that water is pumped from the Delaware River, filtered, used for domestic purposes, filtered again and returned to the river in better condition than it was taken out.

There is one sewage disposal plant: a surface drainage system of two pumping plants using two sewage drying beds and one disinfecting house. The sewage system would take care of a municipality of 30,000 people.

Much of the machinery used in ship construction, etc., is operated by compressed air, which is supplied from 7 compressor houses. The compressor equipment consists of 19 cross compound compressor units direct connected to high voltage synchronous electric motors. The total capacity of this compressed air system is 73,675 cubic feet of air per minute requiring 14,250 horse-power.

The work of constructing the various utilities was carried on under the greatest imaginable handicaps, both as to isolation of location from transportation, water supply, bad drainage, weather conditions, labor conditions, and other causes coincident with the construction of the shipyard being carried on at one and the same time. During the winter months ground was frozen to a depth of 2 feet, and a considerable portion of the excavation required blasting. It was also necessary to thaw the ground by means of steam at times in order to permit excavation.

The terminal facilities at Hog Island are of such a nature that they might be made of great value as another terminal for our eastern coast. In fact, from information gathered from one source or another, it appears that it could be easily made one of the world's greatest terminals and the city of Philadelphia and the state of Pennsylvania would do well to acquire this plant as a site for such a terminal. Hog Island is one of the marked exceptions, in the entire war program in this respect: that is, building will be entirely justified as a terminal, aside from its shipbuilding facilities. Hog Island today occupies the position of being as good a salt water terminal or coast terminal as any in the United States. The terminal exists; and if the United States government wants to commence using it to-morrow morning as a terminal it can do so.

Let us review a few facts in regard to this plant as a terminal. The 26 wooden warehouses and the large concrete warehouse were designed so that they would be available as storage houses in a terminal scheme. Each warehouse is served by a railroad track for the entire length of the house and each warehouse has a platform adjoining a street for its entire length. In other words, each warehouse is available for its entire length to the railroad, to teams and to tracks on opposite sides of the house. The 25 miles of railroad track serves the 148 acres of steel, machinery and outfitting storage yards, and was designed to be available for the storage of any material that could be stored in the open.

In designing the seven outfitting piers, two standard steam railroad tracks were placed on each side of the pier with double cross-overs between each two tracks about the center of the pier. These two tracks serve every ship at the wet-basin piers, which helps in the speed of outfitting ships, and is very desirable when the piers are used as commercial piers in that the track on the outside of the pier can be used for flat cars containing heavy, bulky material and the freight on that track is within reach of the ship's tackle. On the inside track can be placed box cars containing freight which must be unloaded on the pier, and freight unloaded from box cars on the water side of the track is within reach of the ship's tackle.

Each of the seven piers is equipped with four self-propelling gantry cranes running on a wide-gage railroad track, which spans the outside railroad track on each side of each pier. The clearance under this gantry crane is sufficient to permit the operation of standard locomotives and cars. Each of these gantry cranes is equipped with booms 50 to 70 feet in length. In addition, each of the piers is equipped with two self-propelled locomotive cranes, and pier B is equipped on each side with a bridge crane with a span of 118 feet and 111 feet clearance from mean low tide with a lifting capacity of 100 tons, which is used for placing the turbines and reduction gears in the ships immediately after they are launched. The same crane is admirable for placing locomotives and other heavy articles in the holds of vessels.

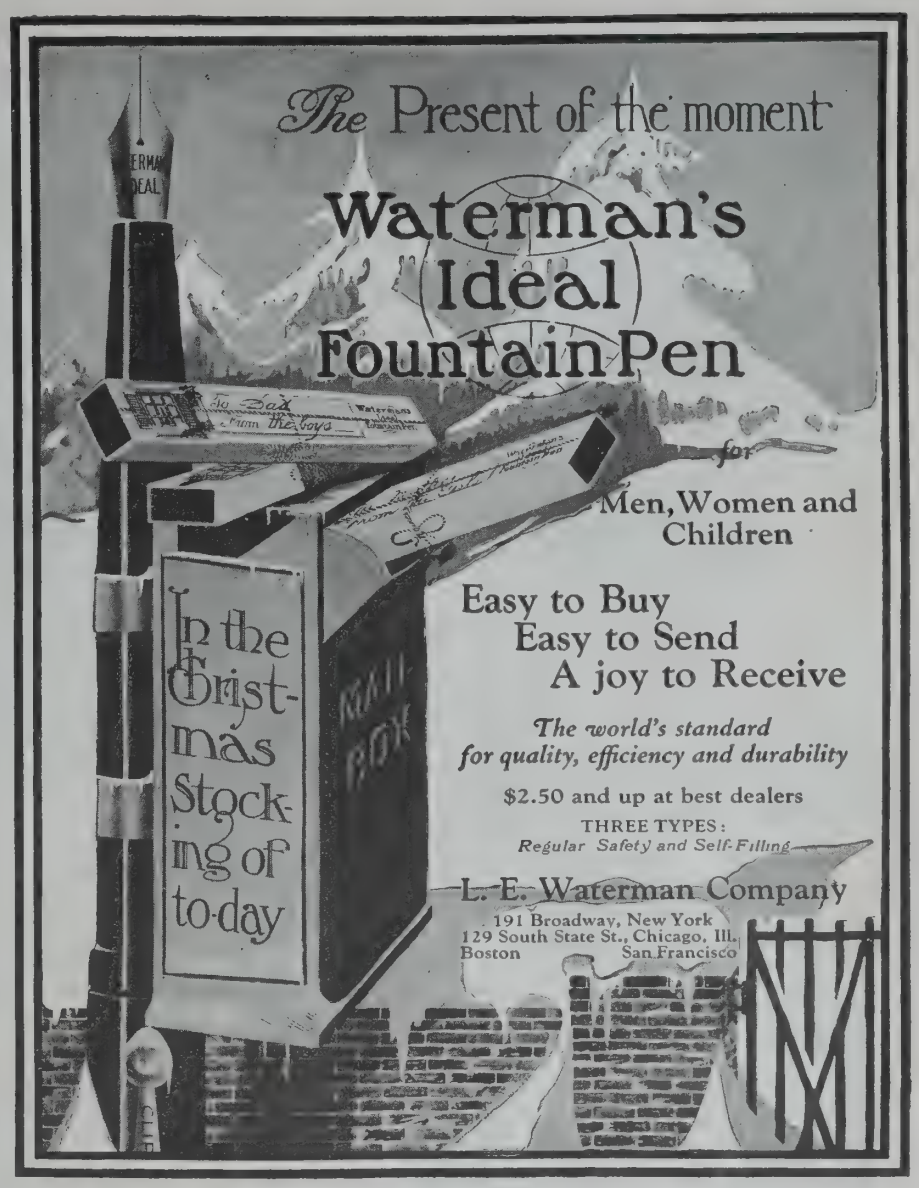
There do not exist at any commercial port in the United States any better equipped storage yards and storage houses or piers for commercial purposes. In fact, at no other commercial piers in the United States does there exist today 50 per cent of the modern appliances for the handling of cargo and the quick dispatch of vessels with economy and speed that are at this minute available at Hog Island with all details so thoroughly and painstakingly thought out and provided for.

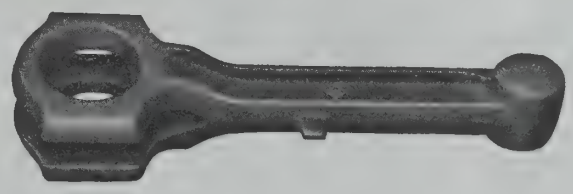
## From Wood to Cloth

(*Continued from page 591*)

minute splinters and particles by being held against grindstones. Strong paper is made from chemical pulp in which the fibers are separated by acid, as in the common sulfite process, or by alkalies, as in the soda and sulfate processes. The so-called "Kraft" paper, the term of Teutonic origin signifying strength, is made from undercooked, nonbleaching, brown pulp. This paper, true to its name, is remarkably strong and resistant to wear and is especially adapted for wrapping purposes.

The manufacture of paper textiles begins with a good grade of thin, tough paper of the Kraft type. This is cut by special machines into narrow ribbons from a sixteenth to half an inch in width, depending upon the size of the thread or yarn desired. The finest thread is made from a kind of tissue paper. These ribbons are rolled into flat, disk-like reels ready for spinning. If a white or light-colored yarn is wanted the paper used is





WILLIAMS' Superior Drop-Forgings have always been termed Superior since the beginning of this business, not in a spirit of smug self-satisfaction, but with a deep sense of our obligation to make Drop-Forgings that are unquestionably Superior in fact as well as in name.

Through nearly half a century this ideal has been maintained. It dominates our entire organization. The manufacturer who uses Williams' Superior Drop-Forgings knows that every effort that human ingenuity can devise has been brought into play in creating drop-forgings that will serve him well.

made from bleached pulp. It is likely to be less strong.

The spinning is usually nothing more than the twisting tightly of a single paper ribbon. Such paper yarn breaks easily and with a short fracture. Sometimes several fine ribbons are spun together or several spun threads are twisted cable-like. Again an inner core of spun paper may be covered with the waste from other fibrous materials such as cotton and flax. The paper yarn may be "processed" to make it waterproof, though the efforts in this direction have not been entirely satisfactory. The best results have been obtained by the mixing of yarns and by tighter twisting of the paper.

There is nothing novel in the weaving process as the ordinary loom, bobbins and shuttles are used. Some textiles are woven entirely of paper yarn, others in mixture with cotton or nettle fiber. Pure paper textiles are rather stiff and coarse and are without nap. They are not suited for hard usage or wear and laundering must be done with extreme care, as wetting makes the "natural" paper cloth very tender. If such goods are to be exposed to the weather it is necessary to impregnate them with some water-proofing substance. The quality of the goods varies all the way from thin muslins and print cloths to heavy canvas and coarse matting.

That Germany found paper textiles of great help during the war is indicated by the wide range of uses to which the material was put. Among these may be mentioned, in addition to clothing, lining for gas masks, bed sheets and covers, straw mattress ticking, sand bags (mixed tissue), bread bags, cloths for wrapping feet (as worn by soldiers in place of socks), mull tissue for dressing wounds, sail canvas, uppers and inner soles of shoes, boot straps, belts, shoulder straps, galloons, braid, markers, insignia for prisoners of war, shoe laces, pack thread, twine and ropes. There were also many household uses such as matting and hall runners, table cloths and napkins, towels, wall covering, curtains, bed covers and sheets, pillow cases, lining and stiffening for clothing, and print goods for dresses and miscellaneous.

The manufacture of paper yarn was not due in the first place to the war, as long before that time, rugs, runners, curtains, wall hangings, twine and especially sacking were made from this material. The need produced by the war greatly stimulated and extended the use of such textiles. Along with the paper substitute for cotton might be mentioned nettle fiber, and the fibrous material of rush, broom and turf. Articles of apparel for men were made out of 25 per cent turf fiber and 75 per cent artificial wool.

Whether or not the paper textile industry has much of a future in store cannot be determined at present. Some of the German writers look upon it hopefully, and one speaks of the obvious significance of the discovery of the use of wood cellulose for "such purposes as sacking, roofing, binding, and for the materials for making pockets and the like." But scarcely for clothing.

## A Giant of Old

(*Continued from page 591*)

brought from a head race at a little distance, but on the opposite side to that on which the power was delivered to the main-shaft. The water passed through a head gate arranged in the race. This gate admitted to a 48-inch brick conduit that led to the wheel. It should be understood that the wheel was set with the one side next to the face of a ledge or terrace. Naturally, this was the side next the head race. From the brick conduit a metal pipe led the power water up a short incline to the summit of the wheel. The pipe was continued on across the top of the wheel—in a direction parallel to the axis. The pipe was then continued downward, but with a greatly reduced diameter.

Perhaps it will be well to insert a brief explanation covering the principal features of an old-time wheel, so that our further consideration may be facilitated. There are five chief parts into which the structure may be divided. There is a shaft or hub, the arms or radial rods, the shrouding, the soling and the floats. The shrouding is the aggregate of the segmental pieces that corresponds in position to that of the felloe in a carriage wheel. The soling is the peripheral face. With the shrouding, it forms a kind of circumferential trough. The soling constitutes the convex flooring. The floats are the blades extending across the convex face of the wheel. They lie in the trough. In the case of the Burden wheel, the power water is fed to the wheel from the pipe length, or cylinder, which extends across its crest parallel to the axis.

The designer of the Troy wheel was Henry Burden, who came from Scotland to the United States in 1821, when he was 30 years of age. The wheel was constructed for the purpose of supplying power to an iron and nail factory whose business had become very considerable. The works were, and are still, located on the banks of a small tributary to the Hudson known as Wyants Kill. Not far away from them was Burden Falls which dropped the water of Wyants Kill a vertical distance of about 50 feet. Below the falls were a number of rapids. Altogether, there was a total available head of about 70 feet. Wyants Kill is the outlet of four lakes located some 10 miles distant. At the works, the drainage available is perhaps 36 square miles. A dam was built in the region of the four lakes and thus created a fifth. This proved to be a solution of the problem of storage and regulation. There would be, in fact, plenty of water at all seasons.

There were, it seems, five small water wheels; but Mr. Burden preferred to construct a single unit of large size. It is understood that construction began in 1838. In its early form, the wheel was operated not without difficulty. About 1851 it was rebuilt. In the earlier wheel one of the journals became excessively heated and broke off. In the rebuilt wheel, hollow journals were employed and provision made for the circulation of water over them. The wheel of 1851 is the same wheel whose south supporting pier gave way a few weeks after the Great War started. Only a few replacements seem to have been necessary. A wooden stave pipe was employed at first instead of the later riveted iron pipe. And about 1882, the segment gearing was replaced. These replacements and ordinary repairs sum up the maintenance of the wheel during a period of forty-five years, the wheel having stopped in 1896.

The dam which provided for the head race was only a few hundred yards above Burden Falls, so that no great length of water-way was required.

The great wheel was constructed mostly of wood. The soling consisted of Georgia pine in heavy pieces 10x10 inches in section. To these the 264 iron rods, which were of 1½-inch size, were secured. On this same soling, on top of the ends, the segmental gearing was attached.

It will be gathered from the foregoing that this great wheel must have been a heavy affair. And indeed, so it was. It is estimated that in a soaked condition the wheel must have weighed about 250 tons, so that 125 tons came on each bearing.

The power multiplication by the gearing was about 35. With the water wheel rotating at 2½ turns per minute, the flywheel would rotate at about 87½ turns per miute. This was the rate considered desirable. With the fluctuations of load in the shop, it was accordingly necessary to readjust the flow of the water in order to maintain a constant speed at the flywheel.

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

**SCIENTIFIC AMERICAN**

Contains Patent Office Notes, Decisions of interest to inventors—and particulars of recently patented inventions.

**MUNN & CO.,** SOLICITORS OF PATENTS

**ORANGES** AND GRAPE FRUIT *From Tree to You*

Send me $3.25—I will express you prepaid East of Mississippi River a Family size carton of Oranges, Parson Brown variety, finest grown. Carton contains ½ crate. Specify large or small fruit wanted. Delicious Grape Fruit, same size carton, same price. 3 Cartons either $9.00. Fruit fully ripened on trees. Safe arrival guaranteed. Ready now. Write for my Booklet.
**C. H. VOORHEES, Box 405, SO. LAKE WEIR, FLORIDA**

Mr. F. R. I. Sweney has studied the Burden wheel, and has calculated its efficiency. He finds that at a constant flywheel speed of 2½ rotations per minute, a horse-power of 278 would be developed at an efficiency of 84.25 per cent. This efficiency relates only to the matter of hydraulics and takes no account of the frictional losses in the gearing.

## The Needs of the Patent Office

(*Continued from page 592*)

vast extent of the developments in the arts as a warning against undue expectations of financial award from the receipt of a patent grant. It would benefit the public and the Office highly if the number of applications and patents granted were cut in two; if trivialities that now burden the processes of examination and the records were substantially reduced.

There are many other improvements that have and could be suggested, such as making the entrance to the patent bar more rigorous, limiting the number of claims in an application, restricting the life of a patent in accordance with its extent of prosecution in the office, etc., etc., but no attempt will be made to further treat this subject-matter than has already been done. It would take a volume to discuss its ramifications in all its phases. An exception, however, to the termination of this treatment must be exercised with relation to one thought. It has frequently been suggested that an exhibit of the more striking results of invention be placed on view in the Patent Office. Such an exhibit of models of the most notable inventions would undoubtedly bring a measure of public interest to the workings of the Office that does not now exist. The Patent Office needs the interest of the public very much. Not only would the public's interest to the benefit of the Office be aroused in a display of the fruits of the highest and most characteristic genius disclosed by the American people, but the public would be reciprocally profited by the receipt of information, in an intensified and never-forgotten form, of the beneficial effect the patent system has had in arousing that genius.

Once the public becomes conscious of the stupendous service to humanity conferred upon it by the activities of inventors, and the relation of the Patent Office to their output, it may not be beyond the limit of imagination to visualize a condition when the expectations as sketched in this paper may actually be realized.

## Surveying America's Snows

(*Continued from page 594*)

stream-flow is the occasional lack of precipitation during April-June after the snow survey has been made. It has generally been considered that small amounts of rain such as usually fall in the semi-arid West have little influence on stream flow. And this is particularly true in the autumn when the rain falls directly upon the soil. However, in the spring when the snow fields stretch far down the slopes of the mountains toward the stream-gaging station, the greater part of the precipitation combines directly with the snow and obtains an "untaxed" passage with the latter into the stream below. Consequently, the lack of normal precipitation in April-June, when the snow fields are melting, causes a shrinkage in the seasonal percentage of the run-off indicated by the snow survey. This problem is met by postponing until the first day of May the final forecast of the stream flow in order to use the precipitation, the temperature, and the run-off for April as factors in determining the subsequent flow.

According to Dr. Church, a fallacy long prevalent has until the present prevented the application of snow surveying estimates to wide areas. This fallacy is the belief that storms are spotted and basins individual in their character so that the snow in one basin is not indicative of the relative amount in the next, and that even the snow cover in one part of a basin is not comparable to that in another.

"While this is particularly true in summer," he went on to explain, "and within narrow limits also in winter, the general correspondence of the stream flow in basins along the axis of the Sierra Nevada for distances of 150 miles, usually on one side of the range and sometimes on both, indicates the similar correspondence of the snow cover. Indeed, over a period of 9 years the usual maximum divergence has been between 8 and 15 per cent. The cause of the close correspondence is doubtless due in large measure to the heavy contribution by the 'big storms' that cover a large part of the range as they pass eastward. Hence, the result of a careful snow survey in any basin can usually be applied within 25 per cent to any other, and a series of surveys at wide intervals along the summit of the range will indicate the direction in which an increase or decrease in seasonal percentage of snow cover is to be expected."

## Wanted: An Inexpensive House

(*Continued from page 596*)

only to selected contractors, who are given exclusive rights in certain territory.

Building one's own home at best these days is costly business. There is no escape through sheer good luck. Here and there some fortunate person may come across an old-fashioned house which requires certain minor improvements to bring it up to date—to make it available for the persons of today, so to speak. There are thousands of such houses throughout the land, which, lacking the very latest word in appointments, are apt to go begging for buyers. As a general rule such old houses include a most desirable piece of ground, with fine fruit trees, shade trees, flowers, hedges, and so on. Such things are priceless in the sense that they cannot be produced overnight to adorn the new home.

Much can be done with old-fashioned houses. With the dismantling of National Army cantonments here and there throughout the country, one can pick up various bits of equipment and material for remodeling old houses. Plumbing supplies, lighting fixtures, wiring materials, wall board, furnaces—all these things are available at low prices at the dismantled cantonments. All in all, an old house is apt to contain better lumber than the newer houses, and if the foundation, sills and main members are found to be in excellent condition, one can purchase such a house with full assurance that one has a good foundation on which to build and improve and finally evolve a comfortable and worth-while home. Here, indeed, is a first-rate opportunity for the man who is handy—and the woman, too, for there are many little touches about such a house that await the feminine mind and hand.

## Venezuela's Mountain-Climbing Oil-Burning Locomotive

(*Continued from page 597*)

| | Coal | Petroleum |
|---|---|---|
| Evaporation of water per single kilogram of fuel | 3.55 kgs. | 4.75 kgs |
| Ashes deposited in the steam box | 20.25 " | none |
| Ashes deposited in the ash-hole | 105. " | none |

"And this, abstracting other advantages in favor of crude petroleum, develops the fact:

"First, better sanitation and cleanliness, in not having to clean the ash-hole, the steam-box, etc., and, in consequence, less labor for the fireman;

"Second, economy of time in the placing of the combustible aboard the locomotive, there being then no necessity for coal;

"Third, economy of fire-wood and of coal

**"Clean! Thoroughly Clean"**

That's what you will say when you use Goblin. This soap—a combination of the purest and most effective ingredients—dissolves every particle of dirt. It frees the pores of grease, grime and stain. When through washing with Goblin your skin is fresh and smooth and clean; a thoroughly clean skin means a healthy skin.

Always keep an extra cake of Goblin on hand for the dirty, grimy job; it'll do the work where other soaps fail.

Go to your grocer and buy a cake of it; test it to the limit; there isn't an injurious element in it to harm or chafe the tenderest skin.

If your dealer hasn't got it send us his name and address and we will send you a trial size cake free.

# A Wife Too Many

Into the hotel lobby walked a beautiful woman and a distinguished man. Little indeed did the gay and gallant crowd know that around these heads there flew stories of terror—of murder—and treason—that on their entrance half a dozen detectives sprang up from different parts of the place.

Because of them the lights of the War Department in Washington blazed far into the night. About their fate was wound the tragedy of a broken marriage, of a fortune lost, of a nation betrayed.

It is a wonderful story with the kind of mystery that you will sit up nights trying to fathom. It is just one of the stories fashioned by that master of mystery

**CRAIG KENNEDY**
*The American Sherlock Holmes*
**ARTHUR B. REEVE**
*The American Conan Doyle*

He is the detective genius of our age. He has taken science—science that stands for this age—and allied it to the mystery and romance of detective fiction. Even to the smallest detail, every bit of the plot is worked out scientifically. Such plots—such suspense—with real, vivid people moving through the maelstrom of life! Frenchmen have mastered the art of terror stories. English writers have thrilled whole nations by their artful heroes. But all these seem old-fashioned—out-of-date—beside the infinite variety—the weird excitement of Arthur B. Reeve's tales.

## FREE—Poe
### 10 Volumes

To those who send the coupon promptly we will give FREE a set of Edgar Allan Poe's masterpieces in 10 volumes.

When the police of New York failed to solve one of the most fearful murder mysteries of the time, Edgar Allan Poe— far off there in Paris—found the solution. The story is in these volumes.

This is a wonderful combination. Here are two of the greatest writers of mystery and scientific detective stories. You can get the Reeve at a remarkably low price and the Poe FREE.

**HARPER & BROTHERS**
Established 1817

Cut out this coupon and mail it today

**Harper & Brother, 21 Franklin Square, New York**

Send me, all charges prepaid, set of Arthur B. Reeve—in 12 volumes. Also send me, absolutely free, the set of Edgar Allan Poe—in 10 volumes. If both sets are not satisfactory I will return them within 5 days at your expense. Otherwise I will send you $1 within 5 days and $2 a month for 14 months.

*NAME*.....

*ADDRESS*.....

*OCCUPATION*.....

Scien. Amer. 12-11-20

and also of time, in raising steam in the locomotive at the commencement of work (cold machine). For this operation there was used in the present case a fixed machine that generated steam, which, by means of a tube was carried to the locomotive. It required 1½ hours to put this in readiness for movement, without the necessity of fire-wood or coal, while for the employment of those combustibles, 3 to 4 hours would have been expended;

"Fourth, economy of steam, and, therefore, an easier regulation of feeding and no functioning generally of the safety-valve of the locomotive by excess of tension; uniformity of tension of the fire-box and ease in sustaining a convenient steam pressure."

Yet another departure in railway operating methods in Venezuela is the substitution of electric trolley for steam power on short, fairly level stretches on the coast, about La Guaira, and on the mountain plateau about Caracas, which doubtless will be followed by like conversion on a larger scale elsewhere in the republic. These suggest further opportunities for American equipment and supply interests.

## Music From Glass

(*Continued from page 598*)

perhaps a goodly total—scattered over the world. They are, in America at least, more of a curiosity than anything else. The sweetness and beauty of tone appears to be undeniable. But, apparently, the quality of the sound is such as to act unfavorably upon the nerves of some hearers. The musical critic, Fr. Rochlitz, in 1798, writes warmly in defense of the harmonica. He thought that it was as little injurious as any other expressive instrument. He recommended restraint in the enjoyment of this variety of music and thought its soft and pleasing tones should not be permitted to occupy the attention too much at night.

The success of the early harmonicas led to the desire to improve and vary. The effort was made to substitute something else for the human hand, but the success appears to have been only an indifferent one. There was difficulty in getting or continuing to get the peculiar and ethereal tone possible with the hand. However, the Abbot Mazzuchi invented a variety of harmonica which substituted the violin bow. The bells were inclosed in a case. It is said that the tones from this instrument were less exciting to the nerves of sensitive people. Another variation from the Franklin type uses little pegs with a pad at the end made of sponge as the means of vibrating the glass.

At the Metropolitan Museum of Art, New York City, there is (No. 1820) an English instrument consisting of 24 glasses standing on feet. There are one or two omissions, but the range appears originally to have been two complete octaves and two notes. At the same museum is an example of the Franklin type (No. 1211). This is a glass harmonica of 35 hemispherical glasses arranged on a rod. That is, the rod is placed horizontally and the various glasses are arranged on it in vertical "planes." This instrument dates back to the eighteenth century. The glasses originally provided a range of three octaves, but there are one or two missing. The diametrical sizes vary from 10½ to 3½ inches, and all are contained in a suitable case.

Benjamin Franklin's harmonica is not to be confused with musical glasses. It is, in reality, a mechanical device and not a mere collection of glass vessels. As this instrument seems never to have been essentially improved, the reader may be interested in learning precisely how it is constructed and operated. I follow Franklin's own account, given in a letter dated London, July 13, 1762.

Thirty-seven notes are desired. But a lesser number of glasses may be used. These are, each of them, approximately hemispherical. At the pole of the hemisphere is a neck not unlike that of an ordinary bottle. The largest diameter is 9 inches, the smallest 3. The diametrical size varies by intervals of ¼ inch; so that altogether there are 25 different diameters. A half dozen or more glasses are to be blown of each size and from these 150 or more hemispheres the 37 desired are to be obtained. The thickness of the glass at the edge is to be 1/10 inch or even less. The glass thickens somewhat as the neck is approached. This neck will vary for the different sizes. In the largest the neck will be, perhaps, 1 inch deep and 1½ inches wide within. The depth of the neck of the smallest glass should not be less than ½ inch. Having accumulated the considerable stock of hemispherical shapes, one is ready to begin the business of getting 3 octaves and 1 note from the lot.

A selection is made with two objects in view. First, one keeps before him the purpose of getting 37 notes that are either exactly the ones desired to make up the range or else are a trifle too sharp. Second, one seeks to get glasses that will fit fairly well, the one within the next larger. Assuming now that the choice has been made, one marks each glass with a diamond in such way as to indicate the note it is finally to utter. The glasses that are too sharp are reduced in pitch by grinding them in a zone of an inch or so in latitude, this zone being next the neck. Naturally, the glass should be tested from time to time to determine when it has suffered precisely the right reduction in pitch. Franklin recommends that as the right note is approximated, the glass be wiped clean and dry before testing, as the tone is flatter when the glass is wet. If the grinding be done by short stages near the finish, great exactness of pitch may be obtained. If, through inadvertence or otherwise, a glass be flattened too much, the brim may be ground off to remedy the matter. But this calls for polishing in order that a smooth surface may be present to the hand of the player later on.

The glasses, once they are tuned, are mounted in proper order upon a suitable spindle. As the general assemblage of glasses on the spindle produces a conical figure, viewed as a whole, the wooden case in which the group is to be arranged may follow this somewhat. That is, the case, while not departing from a form having a rectangular cross-section, may nevertheless taper toward one end. Franklin's case opened along a horizontal plane at a level intermediate between top and bottom. The spindle with its glasses upon being mounted in place was so disposed that upon opening the case the upper halves of all the hemispheres were disclosed. At the larger end of the spindle, a suitable fly wheel is mounted. A treadle is arranged, by suitable connections, so that the foot is enabled to rotate spindle and glasses. The spindle is set horizontally and mounted in brass gudgeons. Franklin's harmonica had a spindle of "hard iron," round in section, and tapering from a diameter of 1 inch at the fly-wheel end to ¼ inch at the other end. The big end is squared for the wheel. Franklin used a mahogany wheel 18 inches in diameter and rather thick—thick enough in fact to conceal a 25-pound weight of lead near the circumference. The wheel had six spokes, apparently. A pin of ivory was set in one and over it was passed the loop of the string connected with the treadle. Franklin states that the pin was located about 4 inches from the axis.

The fixing of the glasses on the spindle is done with the aid of corks. Thus, a cork is fitted into the neck of a glass and is allowed to project somewhat. The object of this projection is to prevent actual contact of glass with glass. When the corks have all been duly fitted, they are perforated to receive the spindle. Naturally, the perforations correspond with the spindle size at the proper location along its length. "When a glass is put on, by holding it stiffly between both hands, while another turns the spindle, it may be gradually brought to its place."

The playing is done by operating the spindle with its complement of hemispheres and laying the finger on the various glasses as the several notes may be required. The brim is the place from which the note is drawn. Franklin recommends that the tone be got by rotating the glasses away from the finger rather than toward it. His instrument had G (somewhat below "a common voice") for its lowest tone and then included all the usual tones in the three octaves above. The fingers are to be soaked in water, and are to be free from all greasiness. A little fine chalk may be used at times in order to bring the tone out the better. A considerable advantage is pointed out by Franklin—once tuned, retuning becomes unnecessary.

## NEW BOOKS, ETC.

THE USE OF COLLOIDS IN HEALTH AND DISEASE. By Alfred B. Searle. New York: E. P. Dutton and Company, 1920. 8vo.; 120 pp.; illustrated.

Ostwald tells us that all life processes take place in a colloidal system; Sir Malcolm Morris, in his foreword, reminds us that this is equally true of normal body fluids and secretions and of bacterial toxins. If, then, medicines were administered in a colloidal state, careful investigators conclude that their remedial value would be higher. This book tells what results have already been achieved, and how scientific chemistry may surmount the difficulties presented by the instability of colloidal substances. It is a valuable contribution to a growing school of thought.

WHAT BIRD IS THAT? By Frank M. Chapman. New York and London: D. Appleton and Company, 1920. 12mo.; 144 pp.; 301 birds in color.

To the nature lover, the question put by this title is constantly recurring. In this unique little guide, the Curator of Birds in the American Museum of Natural History makes it easy to identify our feathered friends. His exceptional facilities have been drawn upon to the fullest extent, and the result is a work picturing and describing every land bird east of the Rockies. We have the distinguishing marks, range, nest, eggs, and song of each, and the localities and seasons where and when it may be looked for. The original treatment will at once strike the enthusiastic amateur.

THE NEW MERCHANT MARINE. By Edward N. Hurley. New York: The Century Company, 1920. 8vo.; 296 pp.; illustrated.

Mr. Hurley, having served his country to such splendid effect as chairman of the Shipping Board and president of the Emergency Fleet Corporation, leaves this book as a monument to our intensive achievements and a guide to future policy. With the history of American shipping as a background, his stage is occupied by sound suggestions. We have perils to avoid and opportunities to develop; these two objects are greatly forwarded by the thorough knowledge of conditions this work offers the foreign trader and the general reader. It enables us to think in terms of the future, and to shape the policies of the present to eventual supremacy on the seas of peace. It is ships that are rebuilding civilization, and ships that must protect and maintain it.

LANGUAGE FOR MEN OF AFFAIRS. Vol. I. Talking Business. By John Mantle Clapp. Vol. II. Business Writing. Edited by James Melville Lee. New York: The Ronald Press Company, 1920. 8vo.; 1192 pp.; illustrated.

Vol. I., 'Talking Business," deals with the special language problems of the business man. How he puts his proposition often means success or failure; he cannot rely entirely upon the merits of his case, for his rival's probably has a few merits of its own. He must know how to best bring out the strong points and overrule objections, all in a winning and human way. Vol. II. exhibits the technique of business letters, reports, and advertising copy. The articles are written by men who are one with their subject. To catch the attention and subtly guide the mind of the prospect is a fascinating occupation that is here set forth step by step with thoroughness and clarity. The man who would increase the power of his tongue and his pen cannot do better than turn for help to this substantial work.

# The Right Rubber Product in the Right Place

AS the world's largest manufacturer of mechanical rubber goods, the United States Rubber Company is vitally interested in the correct application of its products throughout industry.

It has too large an investment at stake in its mechanical rubber factories to compromise on quality or service. Every product must deliver the maximum days of service for every dollar that it costs the purchaser.

To insure the application of the right U. S. mechanical rubber product to any given condition, our large force of representatives — practical men of broad experience — are at your disposal.

*Left:* The induction motor which, at 100 revolutions per minute, develops 3,000 horse-power for driving the single screw. *Center:* The steam turbine and generator unit which supplies alternating current to the single induction motor. *Right:* Chief Officer of the "Eclipse" at the safety steering device on the bridge. One man can control the movements of an electrically-driven vessel almost as easily as a motorman can drive a street car

**Some features of the electric drive used aboard the S. S. "Eclipse," one of eleven Shipping Board freighters to be so equipped**

## Electric Propulsion for Our Merchant Marine

EVIDENTLY, electric propulsion of ships has reached that stage in the development of a new art at which general recognition of its value is shown by rapidly extending use. The latest proof of this is shown in the fact that within a few weeks, the United States Shipping Board steamship "Eclipse," which is being fitted with electrical propulsion, will be placed in service. This is one of eleven other freighters of the Shipping Board's fleet which are also being equipped with the electric drive.

"Eclipse" is a vessel of 11,868 tons. The electric propulsion plant which is being constructed by the General Electric Company has been installed and the vessel will soon be placed in service. The plant consists of a steam turbine generator, directly connected to an alternating current generator, the current from which is fed to an induction motor on the propeller shaft, which at 100 revolutions per minute develops a shaft horse-power of 3,000. One of the great advantages of the electric reduction gear is that the speed of the ship and its general maneuvering, so far as the motive power is concerned, can be controlled from the bridge by means of the safety steering device which is shown in one of our illustrations. The bulk of the Shipping Board fleet is equipped with the mechanical reduction gear, and when a considerable number of these electric installations are in service, it will be possible to make some interesting comparisons of the two methods and gather additional valuable data as to their respective efficiency.

Driving a ship by electricity means revolving the propeller shaft from a motor just as trolley cars are driven by motors on the car tracks. To supply "juice" to turn this motor, a generator must be operated somewhere else in the boat, just as generators in power houses make current for street railways. On shipboard these generators may be driven either by an economical steam turbine or by a Diesel engine.

The records of the battleship "New Mexico," the U. S. Navy's first electric ship, show that oil consumption is lowered about one-third by the electric drive, while a greater and more flexible power is attained with far simpler mechanism requiring fewer operatives. It is even possible for the gigantic "New Mexico" to run at cruising speed with an engine room crew of one man, the electric mechanism requires so little attention. Of course, the great battleship will never operate so short-handed, except in emergency, but it can be done.

The idea of driving a huge merchant ship through the seven seas almost with the ease a motorman drives a street-car through city streets may seem humorous, but there is no humor in the basic scheme. It is not only possible for an officer to run his boat with small levers on the bridge, but this is being done. The economies of utilization of hull space, and of fuel are such that students of shipping are beginning to realize what the electric drive means for the rising merchant marine of this country.

Strange to say, however, the first application of the electric drive principle was made on a type of vessel closely resembling the merchant ship, although in reality it was a naval collier—the U. S. S. "Jupiter," launched in 1912. The immediate success of this installation was what paved the way to the adoption of the electric drive in the navy where all of the capital ships of the future will be thus propelled.

**The "Cuba"—first electric-drive passenger ship. The sister ship to the "Cuba" is the "Florida"**

## Synthetic Benzine

THE remarkably interesting and important announcement was made in *Flugwelt* that certain German scientists have succeeded in producing synthetic benzine. It has been found that in the presence of the coal tar of lignite and when heated under a high degree of pressure, hydrogen combines with the hydrocarbides contained in coal tar.

This discovery was made in the laboratories of the Badische Anilin u. Soda Fabrik. The general statement is made that it has been found possible to produce hydrocarbides analogous to those found in petroleum by means of high pressure, taking carbon monoxide and hydrogen in the presence of suitable catalyzers.

*The object of this journal is to record accurately and lucidly the latest scientific, mechanical and industrial news of the day. As a weekly journal, it is in a position to announce interesting developments before they are published elsewhere.*

*The Editor is glad to have submitted to him timely articles suitable for these columns, especially when such articles are accompanied by photographs.*

## The Assured Future of the Automobile

A THOUGHTFUL survey of our modern civilization, as expressed in the broad field of engineering, teaches us that there are certain industries, which because of the enormous benefit they confer upon mankind, become so thoroughly interwoven with the fabric of human life and activity, that they may be considered to be as permanent as civilization itself. In proof of this statement, it is sufficient to mention the railroad and the steamship. Eliminate both or either of these, and civilization, as we know it today, would cease to exist.

And what steam has done for transportation during one hundred years of development upon sea and land, the internal combustion motor has equaled, and in some respects excelled, in a brief twenty years of development upon the hitherto neglected highways of the country. This astonishing fact is little understood by the general public, so let us look at a few of the incontrovertible facts.

There are today in the United States some 7,000,000 motor vehicles. If we assume a conservative yearly mileage of 3,000 miles per car, the total mileage must be 22,000,000,000 miles per year; and if we assume an average of three persons per car, we arrive at a total passenger mileage of 66,000,000,000 miles. Compare this with the figures for 1919 as given out by the Association of Railway Executives, which claim a yearly passenger mileage of some 46,000,000,000 miles. So that this lusty young giant in the field of transportation has a total passenger mileage to its credit nearly 50 per cent in excess of that on our entire railroad system, with its 260,000 miles of track.

Again, in 1919, automobiles, on a basis of 300 days in use and an average of only two persons per car, carried 4,535,000,000 passengers. Compare this with the latest Interstate Commerce Commission figures which show that the railroads carried in 1918 1,124,000,000 passengers, or one-fourth of the number carried in automobiles.

But, says some doubting Thomas, you are comparing two vastly different things; automobile riding is for pleasure—mere junketing, whereas railroad travel is serious—a business necessity. He will tell you that the automobile "craze" will have its day like the bicycle craze, which is as dead today as a door nail. To this it is sufficient to say, first, that the bicycle passed into seeming eclipse because it was overshadowed by the automobile and second, that statistics show the bicycle industry was never more flourishing than it is today, more bicycles being manufactured yearly than there were in the palmiest days of the nineties.

But the real significance of the automobile, as a leading utility in our industrial and social life, has recently been determined by a questionnaire conducted by the National Automobile Chamber of Commerce, which was sent to automobile license holders, selected at random from the registration lists of ten widely separated States. The answers received in reply to the first 10,000 cards of this survey are very illuminating, since the results may be considered to be highly authoritative and reliable.

We find that 10 per cent only of the cars are used exclusively for pleasure and that 90 per cent of them are used more or less for business; that 60 per cent of the average car mileage and no less than 78 per cent of the farmer car mileage is to be credited to business; that 34 per cent of the average mileage represents the substitution of the automobile for the trolley or the railroad and the use of the car where there is no other means of communication; and lastly and most important of all it is found that the average car owner, according to his own testimony, adds 57 per cent to his output through use of the automobile, and that the farmer adds 68 per cent to his efficiency.

Now consider the fact that more than 2,300,000 families have been enabled to live in the suburbs or otherwise improve their home surroundings, and that a working force equivalent to 1,600,000 laborers is being applied to farming, and we think it will be agreed that so far from the automobile being a mere instrument of pleasure, it is an instrument of utility that has woven itself so closely into the fabric of our modern social and industrial life, that it has become beyond all question a permanent part of our civilization.

Furthermore, we must not forget that in bringing these material benefits to the individual, the automobile has been responsible for the creation of an industry whose growth has been so phenomenal that today it stands as easily the second largest in the country. Thus, the capital invested in the automobile industry for 1919 exclusive of parts and accessories makers was $1,015,443,338, and in the same year the total motor vehicle production was 1,974,016. The value of this product was $1,885,112,546, which is equal to the value of the total annual production of anthracite and bituminous coal in this country. The industry employed 300,000 men in the production of motor cars and motor trucks, and its annual payroll was $374,933,856. With such figures in mind, no one will be disposed to question the statement of a well-known authority that "the greatest single new productive force in the development of the United States in the past twenty years has been the automobile."

Today the automobile industry, in common with all others, is passing through a period of readjustment, and there are many indications in the case of this particular industry that the readjustment is nearing completion and that early in the coming year everything will be in full swing upon a new and more solid basis. Of this we may all be assured, that there is not now nor has there been at any time any question of the permanent prosperity and the continued future growth of the industry. It is estimated that if the car market were confined merely to replacements, over 1,000,000 new automobiles would be needed every year. There are, as we have said, some seven million cars in the United States. There are in all Europe only about one million cars. It is the belief of automobile men that not until the rest of the world has as many cars as the United States will the industry in this country experience anything more than a temporary abatement in the demand. Should the day come when Europe, like America, has seven million cars, there will be a demand, merely for replacements, which will be from two to three times as great as the maximum number of cars that has ever been turned out in a single year.

## Shipbuilding Here and Abroad

AT the present time, according to statistics recently issued by *Lloyd's Register*, there are being built in the United States 312 vessels with an aggregate gross tonnage of 1,772,193 tons, as compared with 767 vessels aggregating 3,470,748 tons which were under construction in the corresponding period of last year. That we were building this fall not much over half of what we had in hand last fall is of course due to the fact that the great program of the Shipping Board is being rapidly completed, and no additional vessels are being laid down by the Board. An interesting fact is the large number of tankers which are now under construction. The United States is building 79 of these, of 545,302 total tonnage, and the United Kingdom is building 32, with a total tonnage of 232,758. Three other tank steamers are being built in other foreign countries.

Lloyd's statistics show that the United Kingdom is regaining her pre-war position in the world of shipbuilding. At the end of September this year, 961 ships were being built in British yards, and their total gross tonnage was 3,731,098 tons, an increase of 914,000 tons over the amount that was building a year ago. This represents an increase of 32 per cent for the year, and of over 90 per cent as compared with the figures for September 1913. Note should be taken of the fact that a large proportion of these ships are of considerable individual tonnage. Thus, there are now building in British yards 64 vessels of 10,000 tons or over, 57 vessels of 12,000 tons or over, 25 of 15,000 tons, and 4 vessels of between 24,000 and 25,000 tons.

Next to the United States comes Holland, which has in hand 165 ships of 423,400 tons. Italy is building 156 vessels of 365,313 tons, and France, 89 ships of a total tonnage of 292,608. Japan, with 72 vessels of 262,407 tons on hand, is building less than she was a year ago. Shipbuilding has declined, also, in the British Dominions, which have in hand 89 ships of 213,894 tons.

## Saving Steel in Bridge Design

IN the early, very early, days of engineering in this country, it was customary to speak of the "factor of safety" in a structure. The factor of safety was supposed to express the ratio between the maximum load which was supposed to come upon a structure and the breaking load. Not infrequently in steel structures, this factor of safety was as high as five; and thirty or forty years ago the same rough-and-ready method resulted in that magnificent structural material, the Douglas fir of the Pacific coast, being subjected in bridge work to a stress of only 1,000 pounds per square inch when its breaking strength was not less than 10,000.

A growing recognition of the unscientific character of the factor-of-safety method, coupled with a demand for reasonable economy, led to the substitution of the unit-stress method, in which the maximum stress to which the steel shall be subjected is stated, the unit stress varying according to the particular duty to be performed by the various members of the structure.

For many years past there has been a feeling among engineers that the unit stresses were too low for the highly reliable steel which is now available, and we note that a committee of the American Railway Engineering Association has proposed that the carrying capacity of existing bridges be rated on the basis of unit stresses, ranging up to the high figure of 26,000 pounds per square inch.

Now any competent modern bridge engineer will admit that 26,000 pounds per square inch is a perfectly reasonable figure, provided that the preparation of the strain sheet and the design of the details of the bridge are in thoroughly competent hands, and the inspection of the steel both at the mills and in the fabricating shops is conscientiously carried out by qualified men. A great reduction in the present margin between the working stresses and the breaking stresses can be safely met only if the above conditions are most rigorously fulfilled.

In some very interesting comments on this subject, *Engineering News-Record* lays emphasis upon the fact that the secondary stresses created during the erection of a bridge should receive very close attention if unit stresses are to be raised to the point which has been suggested. Live load stresses are all susceptible of measurement, but to determine secondary stresses, which at present are a matter of much uncertainty, it is suggested that they should be measured by means of gage points applied to the structure before its erection.

During the well-known reinforcement work which was done on the Niagara Railway arch bridge, it was found that gage points can be placed on bridge members for as little as a dollar or two per pair. Since the initial measurements would not add heavily to the cost, our contemporary considers that it should be quite clear that the preparatory work for giving complete future knowledge of dead load stresses in a bridge, and consequently of the total stresses, can be done at a cost so low as to be completely negligible. The alternative to this is to meet the secondary stress problem in a haphazard way by adding more metal to take care of it. It is to be hoped that this very practical suggestion will be followed out. Every reasonable proposal to prevent the use of unnecessary steel in bridges should commend itself to the civil engineer. We look to see this admirable suggestion incorporated in bridge practise.

## Electricity

**The Unusual in Searchlights.**—In a recent issue of *Elektrotechnische Zeitschrift* there appears a description of a decidedly novel searchlight installation aboard German warships. Two plane mirrors are used to throw out the beam of light, the searchlight itself being placed inside the hull of the ship and in a protected position, while the beam of light is passed up through the hollow steel mast of the ship and projected by a mirror at the top.

**A Snap-Switch Handle That Cannot Be Unscrewed** has been introduced by a leading manufacturer of electric appliances. This is accomplished by means of a ratchet built in it. The handle may be substituted for the ordinary handle. The ratchet escapement comes into play when the handle is turned in the reverse direction so that it cannot be loosened or removed. By using a small screw-driver on a screw which is well recessed in the center of the handle, the ratchet is released. These handles may be used to prevent the removal of "dead-front" insulated covers of safety panel switches.

**A New Canadian Niagara Power Project** is described in a recent issue of *The Electrician* of London. The new water-power development, which is now under way, purposes to utilize nearly the full drop between Lake Erie and Lake Ontario and require for maximum capacity practically all the flow now permitted Canada under the international agreement. It is known as the Queenston-Chippawa hydraulic development. The present scheme contemplates the development of 500,000 horse-power and 305-foot head, using ten 50,000-horse-power turbines, five of which have been ordered. A description of this work will appear in an early issue of the SCIENTIFIC AMERICAN.

**Why Clark Standard Cells Fail.**—The causes and effects of the cracking of Clark cells at the amalgam terminal and the formation of gas in the amalgam limb are discussed in Scientific Paper No. 390, "The Two Common Failures of the Clark Standard Cell," issued by the Bureau of Standards, Washington, D. C. The methods employed in an attempt to eliminate these defects are also given. It is shown that the cracking of the cell can best be prevented by a very simple expedient of using a cell blank in which platinum wire previously subjected to the action of zinc amalgam is employed as the negative terminal, and also that the effects of gas formation can be minimized through the employment of the smallest excess crystals required to insure saturation at the highest temperature at which the cell is to be used.

**Aluminum for Telegraph and Telephone Lines** is a subject that has received some attention in Germany, where the scarcity of copper has caused the telegraph administration to investigate the possibility of using aluminum for signaling plants. Difficulties were experienced in finding methods for making reliable joints in cables, resistances of several ohms being often observed on carefully made twisted joints. For bus bars, however, aluminum appears to be just as good as copper. Telephone condensers up to 2 mf. in capacity were made with aluminum foil and paper, with the same exterior dimensions as the ordinary tinfoil and paper condenser, continues *Elektrotechnische Zeitschrift*. On alternating-current tests the aluminum foil condensers were found to have much smaller losses than tinfoil condensers, the power factor of the new condensers being only one-fifth to one-eighth that of the ordinary type.

**Direct or Alternating Current?**—There is a decided tendency among certain groups of European engineers to put all direct-current electrification under a common classification as the "American system," and, accordingly, to assume that direct current is the only form of supply accepted in America for railroad electrification. This tendency is vigorously opposed by an author in *Elektrotechnik und Maschinenbau*. This German author maintains that little stress should be laid on the fact that direct-current supply was chosen for the Chicago, Milwaukee and St. Paul electrification, in view of the peculiar circumstances which affected the choice. First of all, he says, the already existing three-phase transmission lines lifted the burden of transmission-line construction from the backs of the electrification engineers, enabling them to get access to power at any point on the road, so that numerous converter stations could be easily erected all along its length. The author further declares that Swiss and German progress in single-phase traction is very little appreciated in America and that one important reason for choosing direct current for the road mentioned was the lack of time for investigation and trial in a period when any kind of electrification was sure to promote economy.

## Science

**League of Belgian Scientific Societies.**—Thirty-three scientific societies in Belgium have formed the Fédération Belge des Sociétés des Sciences Mathématiques, Physiques, Naturelles, Médicales et Appliquées, with headquarters in Brussels. The federation will aid the several societies in keeping up their publications, provide facilities for international exchange of publications, summon congresses, hold expositions, etc. The president for 1920 is Prof. de la Vallee-Poussin, of Louvain.

**"Physiological Reviews,"** published quarterly in Baltimore, beginning January, 1921, by the American Physiological Society, is the latest addition to the list of scientific journals designed to present periodical reviews of progress in particular fields of knowledge. Instead of abstracting individual papers separately, this journal will summarize and compare results, and a bibliographical list will accompany each article. It will therefore be a publication similar in purpose to *Ergebnisse der Physiologie*, the Harvey Lectures, and others of the same sort.

**The Writings of a South American Paleontologist.**—A complete edition of the scientific writings and correspondence of the South American paleontologist Florentino Ameghino, who died in 1911, is now in course of publication at the expense of the government of the Province of Buenos Aires, Argentina, and under the editorship of Alfredo J. Torcelli. The edition will run to a very large number of volumes, as Ameghino was the author of 179 essays and books, few of which are short while some are large volumes. They are at present difficult of access to most scholars.

**Submarine Photography from Airplanes.**—Writing in the *Geographical Review* on the subject of aerial photography as an aid to geography, Mr. Willis T. Lee, of the U. S. Geological Survey, deals at length with the application of this process to photographing and mapping submarine features. The visibility of objects at great depths in clear water from a point far above the surface has been a well-known phenomenon since the wartime period of "sub" chasing by airplane. It is said that objects 45 feet under water have been successfully photographed, and that with the proper plates and ray filters the presence of submerged objects invisible to the eye is revealed by the camera. It has been found possible to use this method of observation to some extent in detecting and mapping sand bars, shoals, drowned terraces and channels. Mr. Lee presents several photographs illustrating the results of the method. Not all photographs of coast lines reveal these subaqueous features. Certain conditions of the atmosphere and the water seem to be necessary for photographing them. "In studying the underwater features as shown in photographs," says the writer, "caution and careful checking in every possible way are necessary. Changes in hue in the photograph might be due to sediment in suspension rather than to differences in depth of water."

**Aridity as an Asset in Agriculture.**—The idea that an arid climate is a blessing to the farmer will strike most people as novel and paradoxical, but a good case in favor of this idea can be made out. In a valuable report on the Columbia Basin Irrigation Project, published by the State of Washington, the following facts are set forth regarding the influence of aridity on agriculture: The almost continual sunshine accelerates plant growth. The soil, constantly warm, prevents any cessation of root activity which would follow night chilling if cloudy weather prevailed in the daytime. An arid climate reduces harvesting costs and insures a higher quality of products, harvested without delay or spoilage by rain. The main point brought out, however, is that, with irrigation as a substitute for rainfall, water can be applied to the crops at the right time and only at the right time; also in just the right amounts. This fact is in accordance with current ideas in agricultural meteorology concerning the great importance of "critical periods" in the growth of any crop plant, when its exact requirements in respect to heat or moisture must be met in order to get the best results. The ideal plan would be to dispense with natural climate altogether and to grow all crops under controlled conditions of temperature, moisture, and probably other atmospheric factors. The above-mentioned report says: "The scant rainfall of the Columbia Basin area has been very beneficial for the future irrigationist. There has not been sufficient moisture to leach away the stored plant food, and at the same time adequate drainage has prevented the accumulation of alkali salts, which are the most soluble of the earth's constituents and are frequently found in poorly drained arid regions."

## Automobile

**England to Motorize Mails.**—There are indications that the General Post Office of England is considering a great revival and extension of motor services for mails, particularly in the more remote country districts. As will be remembered, there was considerable progress in this direction during the years immediately preceding 1914. The war, however, necessitated considerable changes, resulting in a wholesale abandonment of road services and a reversion to "as you were" conditions. Efforts are now being made to recover the ground thus lost.

**Peoria Taxes All Wheels.**—The city council of Peoria, Illinois, has adopted a new wheel tax ordinance effective October 1. Even bicycles and tricycles, ridden by children, must pay a tax of $2 a year. The scale for horse-drawn vehicles ranges from $2.50 to $10; motor buses, $10; motor vehicles, not motor trucks, $4 to $8 a year; and motor trucks, $5 to $15, according to horsepower. Firms engaged in manufacturing or dealing in motor vehicles will be required to pay an annual tax fee of $6 for every dollar's license fee issued. There is much opposition to the measure, but the council holds that the conditions of the public finance forces the action. This action is unusual in that all vehicles are taxed. The usual procedure is to tax only motor vehicles and allow other users of the highways to use them without payment of any fee. It is hoped that other communities figuring on levying a wheel tax will include all vehicles and not make the motorists bear the entire burden as is the established custom.

**Hauling Mill Work by Truck Profitable.**—In the average wood-working plant there are two uses for the motor truck. One is to truck in lumber or raw material and the other is to truck out the finished product—that is, to make deliveries to the purchaser. The trucking-out proposition has more to it than many a wood-working plant has so far developed; it is practical and economical to make truck delivery over comparatively long distances if the road permits it. Investigation into truck service and cost bring to light the fact that in competition with short railway hauls, one can truck millwork and other items in manufactured wood at a greater saving than he can truck such heavy items as sand, gravel, cement and brick. The reason is that the heavy items take a very low freight rate, which motor trucking must compete with, while manufactured woodwork takes a comparatively high freight rate, consequently it can often be delivered by truck fifty or more miles more economically than shipping by railroad and there is a saving of one or two handlings.

**Riveting Ring Gears.**—Where the ring gear is attached to the differential housing by rivets which have become loose, the first step is the removal of the old gear by chipping off the rivet heads with a sharp chisel in order to drive the old rivets out or to drill out the rivet head if this is of the countersunk type. After the rivets have all been driven out and the old ring gear removed, the flange on the differential case should be carefully gone over and all upstanding burrs should be smoothed down with a file. Any irregularity on the flange will result in the ring gear being out of true, as far as its meshing with the driving pinion is concerned. Hot riveting is preferable to cold riveting because when the rivets are put in red hot they fill the holes better as they are headed over and additional holding power is secured by the cooling shrink. In order to make a neat job of riveting it is imperative to use a rivet set. A skilful mechanic may be able to form up a head with a peening hammer but this at best is a slow job and there is always some danger of injuring the differential casing or the gear teeth should the hammer slip.

**Tightening Bearing Cap Bolts.**—A point to observe is to make sure that the heads of the bolts are imbedded solidly in their proper position and that they are not raised by any burrs or particles of dirt under the head which will flatten out after the engine has been run for a time and allow the bolts to slack off. Similarly, care should be taken that there is no foreign matter under the brasses and the box in which they seat. To guard against this the bolts should be struck with a hammer several times after they are tightened up, and the connecting rod can be hit sharply several times under the cap with a wooden mallet or lead hammer. It is important to pin the brasses in place to prevent movement, as lubrication may be interfered with if the bushing turns round and breaks the correct register between the oil hole in the cap and brasses. Care should be taken in screwing on the retaining nuts to insure that they will remain in place and not slack off. Spring washers should not be used on either connecting rod ends or main bearing bolts, because these sometimes snap in two pieces and leave the nut slack. The best method of locking is to use well-fitting split pins and castellated nuts.

# Power and the City

## Some Facts and Figures on How Los Angeles Has Harnessed the Distant Mountain Streams

By Crittenden Marriott

A FEW years ago, when Los Angeles completed its 235-mile aqueduct to bring water from the mountains, a great deal was published concerning the magnitude of the work and the benefits that would follow its creation. It is safe to say, however, that few people noted and that fewer still have remembered that one of the great objects to gain which the people of Los Angeles spent $24,500,000 was the development of hydroelectric power.

Nearly everyone in the East thinks of an aqueduct merely as a means of obtaining water for drinking and other domestic uses—and in the West, perhaps as an adjunct in near-city irrigation. But when these primary needs have been met that of power remains. A great industrial city depends on cheap power as much as it does on drinking water. Coal is lacking in the West; and though fuel oil is at present abundant it will not last forever. But water power will.

The builders of the aqueduct realized this, and one of the objects of their work was to develop water power and to transmit it electrically to the city in order to build up there a vast industrial system. Today this object has become paramount; and the possibilities of the situation can no longer be blinked at. The bald facts are that Los Angeles today has 41,000 horsepower, municipally owned, in use and for sale; and before the close of the present year it will have 98,000 horse-power. And this is only about one-third of the power available from the aqueduct and its adjuncts, the other two-thirds waiting only on the installation of the necessary power-plant machinery to be available for use. This enormous potential power is due to the great fall between the intake of the aqueduct and the city and to the fact that the same water can be used over and over again, the total fall effective for power use being 1,960 feet. Its development has changed the destiny of Los Angeles, transforming a commercial city, dependent almost wholly on the agricultural and horticultural output of its "back country," into an industrial city whose possibilities are unlimited.

The reliability of the aqueduct power has just gone through a very severe natural test. For three years the Southwest, and the Pacific coast especially, has been going through a very unusual drought; and the rainfall for the winter of 1919-20, though far above that for the three winters preceding, was only just about normal. The State Railroad Commission, which in California has control of the water power of the State, has this year sent out an appeal to all power plants to utilize all existing power in the State to the utmost and not to let any available water run to waste. It has even been suggested that all the power plants in the State pool their resources for the common supply. Of all the plants the Los Angeles aqueduct alone was able to turn over a large amount of power to other companies for distribution and use outside the city.

So far as the water itself is concerned, the city, during the three years' drought, has greatly enlarged the suburban area to which it supplies water for irrigation; and it has just allotted for the use of the huge automobile tire factory (operating 33,000 spindles) which is about to begin operations, a supply of water double that used by the entire city of San Diego for all purposes. The total aqueduct discharge is 400 second-feet, equivalent to 258,000,000 gallons daily, which, in addition to supplies already developed locally, gives a total daily delivery of 325,000,000 gallons.

Of course the generation of hydroelectric power outside a city does not necessarily mean that the power is or can be reliably transmitted to the city workshops. However, all aqueduct power so far developed, and much of that not yet utilized, is or will be generated at plants that are very near the city and transmitted over lines whose capacity is far in excess of present loads. The lines to the city carry 100,000 volts; the city is encircled by duplicate 33,000-volt transmission lines (which extend to the harbor district at San Pedro, 16 miles away); and the industrial parts of the city are well provided with distribution power lines.

But what actual use has been made in a big way of the power that became available in some degree for the use of the city of Los Angeles three years ago?

Naturally the demand for domestic, office, street and home lighting had first to be met. After this came the steadily increasing demand of existing industries, large and small, including both those that changed their plants from oil-burning to electrical and those that bought the cheaper power offered by the city in place of that which they had theretofore bought from the two private power plants in the city. The difference in costs now and before the war makes it difficult to compare oil-fuel costs with electrical costs. However, a very careful estimate made by the local ice companies shows that their change to electricity has enabled them to save enough to cover the increase in wages of the last three years, the cost of treating the water, and the interest and depreciation on the new investment. In other words, electrical power at aqueduct rates has held the cost of ice making in Los Angeles to its pre-war standard; and the same is true of many other branches of industry.

After existing needs were supplied, special attention could be given to supplying new plants built for the most part by industries that until then had been unknown in southern California.

As a rule men are pessimists when they are asked to transfer their business to, or to invest their money in, a region where no pioneer has marked the way for their particular line. At the very least they want time to consider. And it takes time to build factories, especially nowadays when both materials and labor are scarce and costly.

Nevertheless the vast advantages of cheap electric power of the aqueduct proved a powerful magnet. Since the power became available many small plants and some huge ones have been built and have gone into operation; others have nearly completed building and will start work during this summer or fall; and others have only just begun building.

The first great industry to succumb to the attraction of the magnet was that of ship building. The two big

The giant Staaken monoplane which carries a crew of two pilots and two mechanics in a cockpit atop the fuselage, and eighteen passengers in the comfortable cabin

## The Unusual in Passenger-Carrying Airplanes

By Alfred Longville

SOME very radical changes are being introduced in aviation of late. Just as we had settled down in the comfortable belief that the passenger-carrying airplane, to be truly orthodox, had to have a number of engines each of which drove its own tractor or propeller screw, along came several new machines which cast aside our fond beliefs and start aviation off on a new course. He would be a brave prophet who would attempt to picture the winged passenger-carrier of the future, in view of the many new and promising ideas now being worked out.

The latest F.I.A.T. 12-seater biplane is a leader among the aeronautical revolutionists, so to speak. Instead of following the accepted practice of a multi-unit and multi-screw arrangement for the propulsion, the engineers of the Fiat organization have designed their huge machine with a triple-engined power plant mounted in the nose of the fuselage and driving a single tractor screw, as in the usual single-engined tractor machine of the 2- or 3-passenger class. In the new F.I.A.T. machine the engines are mounted side by side, each driving the single tractor screw through a gear box. Should any one of the three engines develop trouble, it is automatically thrown out of engagement; furthermore, simple arrangements are provided so that the pilot or mechanic may disengage any one of the three engines, thus enabling certain repairs or adjustments to be made while in flight. The combined horse-power of the three engines is 900 at 1,850 revolutions per minute; but the normal power developed during cruising flight is 700 horse-power at 1,600 revolutions per minute, giving a speed of 115 miles per hour instead of 125 miles per hour at full power. With two of the engines in operation 600 horse-power is obtained, which is ample to maintain cruising speed. From reports it appears that the Italian engineers have solved the problem of a suitable gear drive in a somewhat different fashion from certain French designs in which two or more engines are arranged in tandem to drive a single tractor screw.

Another departure from standard airplane design is the great German monoplane which forms the cover illustration of this issue. This odd machine is the German "Staaken," built in one of the Zeppelin works where efforts of late have been concentrated on the airplane instead of dirigible type of airship.

The most striking feature of the giant "Staaken" is the arrangement of the engines. Following the lines of the all-metal construction of certain German machines, the "Staaken" has an exceptionally thick single wing which is so braced internally, between the top and bottom surfaces, as to require practically no external bracing. The engine units are mounted in the leading edge of the wing, two on either side of the fuselage, offering a minimum of head resistance. In all, the airplane has somewhat over 1,200 horse-power, and carries 18 passengers and a crew of 2 pilots and 2 mechanics. The nose of the machine is hinged and swings back so as to form a doorway into the cabin situated in the forward part of the fuselage. The pilots and mechanics sit in a cockpit on top of the fuselage and above the single plane, which position affords excellent visibility in almost all directions.

The giant "Staaken" is the outcome of a whole line of giant airplanes developed by Germany during the latter part of the war, and intended for long-distance bombardment of Allied cities and military depots. The all-metal construction is carried out in duralumin. The span of the single wing is 105 feet. The speed of the machine is given as 130 miles per hour, which is exceptionally fast for a machine of such large proportions and great carrying capacity.

## Demolition Material as Fertilizer

AT the present time when fertilizer is so much in demand, various materials which could be used for this purpose should not be overlooked. From a French source we find it recommended to use lime and plaster material coming from demolitions, and it contains very useful fertilizing ingredients. Such material can find a very good use on land which is poor in lime and which is situated in the region around good-sized towns. The cost is scarcely anything, and the haulage to the spot would be practically the only

Giant Staaken machine in flight, carrying eighteen passengers with all the comforts of a railroad coach

expense. Material from demolition consists of dry mortar with some fragments of stone, that is, as regards the waste products which cannot be used again. The composition of mortar will be seen by observing how it is made up in the first place, mortar being formed in fact of sand and lime in varying proportions according to use. In general the makeup contains 30 to 40 per cent of lime which afterwards becomes partly transformed to carbonate of lime or chlorohydrate and nitrate. Nitrification is found to be most active in the walls of the ground floor, and there is also formed in many cases nitrate of potash. It will thus be observed

Nose of the Staaken machine, showing the hinged front which swings back so as to give access to the passenger cabin

that this material is rich in nitrates, and it can therefore be employed to advantage as a calcareous fertilizer and as a source of valuable nitrogenous substances. From the sand which it contains, this material is best adapted for use on clayey soil than on sandy soil. In fact, after the lime and the different fertilizing substances have disappeared, either absorbed by the plants or drawn off by water, the sand will remain in the soil and it acts to increase the mobility of light earth which would be a disadvantage, while it is precisely this lightening up which is desired in heavy soils of a clayey nature, hence the sand is very useful in the latter case. The material is found to have a specially good effect on meadows and wet pasture land which however is not of a marshy nature. It is favorable to the growth of vegetables such as beans, peas and the like on ground of this class. Such fertilizer is also good for plowed ground, and here the material should be incorporated at some depth in the soil and not spread on the surface, especially on damp soil, for this would reduce their effect. Aside from mortar and the like, we should also consider the use of plaster coming from demolitions. Its action as fertilizer is not as yet very clearly defined, but it is considered that this material acts not only as a lime fertilizer, but also has an effect due to the sulfur which it contains. On the other hand, it is probable that it facilitates the absorption of potash by plants and favors nitrification. In any event, its effects are noteworthy upon certain crops, such as pod vegetables (peas, beans), clover, buckwheat and others, and it increases their output considerably. Grapevines show its action to a marked extent, but root vegetables and cereals hardly at all. Plaster therefore should not be neglected, for it can be a source of great benefit to crops in many cases. Plaster material should be well pulverized before use as such plaster will usually contain various impurities such as pieces of stone, brick, mortar, etc. The amount to be used on the soil will of course vary according to the case.

## Making New Blood

A VERY remarkable discovery with regard to the blood has just been made by Dr. W. J. Penfold, director of the Australian Commonwealth Serum Institute, London. In the making of diphtheria and other serums considerable quantities of the plasma or fluid portion of horses' blood is used at the institute. The practice has been to allow the blood, after it has been drawn from the horses, to stand for some time to allow the red corpuscles to settle to the bottom. The fluid is then drawn off and used while in the past the red corpuscles have been thrown away. This struck Dr. Penfold as an economic waste so he began experiments in the way of injecting the corpuscles into the horses again. The results have opened up a new chapter in the study of the blood. It appears that the horse can easily and quickly form new fluid if the red corpuscles are put back into the blood. While the normal average amount of blood in a horse is 36 liters it has been found possible to take 48 liters in a week from a horse to which the red corpuscles are returned and that without its vitality being any more, if as much, affected as was the case with ordinary limited bleeding. The practice of returning the corpuscles has been extended to all the horses, between 30 and 40 in number, which are bled at the institute and wider experience is confirming the results of the earlier experiments. The composition of the blood remains practically normal.

It will take some time to realize anything like the full possibilities of so new and startling a discovery but it is bound to have an important bearing on the practice, as well as on the theory, of medicine. For instance there are diseases in which good results might be expected by an injection of the blood of those recovering from the disease but under present conditions the convalescents cannot spare the blood.

# Succeeding in Signal Engineering

## A Relatively New Field Opened to the Man Who Wishes to Learn While He Earns

By Raymond Francis Yates

SIGNAL Engineering is one of the newer specialized branches of railroad engineering. The problem of safe, reliable automatic signaling grew with our railroad transportation systems and today thousands of men trained in this work are employed in the design, construction and maintenance of signal installations. The signal engineer has come into his own during the past twenty-five years and today he takes his place on the engineering staff of all the important railroads.

The profession of the signal engineer is just as important as that of any other trained man on the staff, since his work is to devise ways and means of protecting life and property in transit over the railroads. This country, with its vast transportation systems, suffers considerable loss of life annually not through faulty signaling but through the human factor. Some of our most terrible railroad accidents have been caused by the engineer going to sleep or dying at the throttle. The signal operator is not infallible and some very serious accidents have occurred through neglect in this part of the present-day system.

When the engineer is asleep there is nothing to prevent the train from passing a signal. On the other hand, if the signal operator makes a serious mistake there is no way for the engineer to know it. These imperfections in the railway signaling systems of today have caused a great many lives to be sacrificed, and one of the most pressing needs of our railroads is a perfect automatic system that will almost, if not quite, eliminate the human factor.

While the railroads were under Federal control the problem of automatic signaling was put in first place among improvements. Experts claimed that the need was for a system similar to that in use on the New York subways. When a subway motorman passes a signal, the brakes are automatically applied and the entire train is stopped within a few feet. Of course, this system as it now stands cannot be applied to steam railroads, because the problem is not exactly of the same nature.

One reading the foregoing lines can easily recognize the future of signal engineering. Although the field is not extremely broad, it is nevertheless promising and holds a good future for those who master its details. There is especial need for men of an inventive turn of mind.

Mr. T. G. Cooke of the School of Applied Engineering of Chicago, Ill., is the Director of the Department of Signaling, and the writer decided to obtain his views on the subject, knowing that his long experience and standing in the field would enable him to give some very valuable and encouraging information to the young men who are surveying the field with the hope of entering this profession. The information imparted in the following lines is given through the courtesy of Mr. Cooke. Nothing but honest opinions are given and there has been no effort on the part of the author or Mr. Cooke to make the field appear more than it really is.

The first matter of importance in reviewing any field is education. The majority of signal engineers today are not college men. This fact certainly ought to encourage the young fellow who has an interest in the field and who cannot see his way clear to attend school. The need for signal engineers has been so pressing during the past few years that most railroads are willing to take on any young men to learn the work as far as they can by experience, and if this is supplemented by study the position of signal engineer is reached within four or five years. This is by no means a "sure-fire" proposition. Much depends upon the man, his ability, courage, honesty, and capacity to do things.

It is the general opinion among railroad officials that a signal engineer does not have to be a college graduate.

Of course, the college man enjoys an advantage over the self-trained fellow, but in this particular field experience counts more than in most professions and oftentimes offsets the advantage of college. A two-year special course in electrical engineering would be a wonderful aid to a man about to enter the signaling field.

One thing that makes it possible for a man to succeed outside of college is the absence of the need for involved mathematics. Mr. Cooke informed the writer that signaling engineering can be taught to a man who has a good, thorough knowledge of arithmetic. For the man who wishes to get out of the "rule-of-thumb" class as far as possible, however, the study of higher mathematics is essential. Work in signal engineering is seldom speculative enough to demand the application of the involved processes of calculus, differential equations, etc. It can be said in general that a knowledge of arithmetic will enable a man to master the details of signal engineering but it will not enable him to lift himself above the crowd who have a similar training.

The subject of signal engineering involves a study of mechanical, electrical and illuminating engineering. That is, the man to be proficient in signal engineering must have an electrical and mechanical education and should have an aptitude for work along these lines. The illuminating work is necessary but most roads at present do not lay so much stress on this as on the other features of the work. Mechanical and electrical work really form the foundation of signal engineering. The work itself in regard to the railroad is divided up into maintenance and construction. Both of these branches are subdivided into such work as testing and repairing, which is both electrical and mechanical.

The design and manufacture of railroad signal equipment is not done by the railroad companies. Several large manufacturers in this country carry on this work. The man who qualifies as a railroad signal engineer with several years of good practical experience will have little trouble in obtaining a position with a manufacturer, providing he desires to enter this phase of the work. The position of designing engineer with a signal manufacturer is one which must be filled by a man who is thoroughly trained. Most of these positions are filled by college men, and the man educated to be either an electrical or mechanical engineer has a splendid opportunity to qualify as a designing engineer after a little experience along this line. A few men who are not college-trained hold positions as designing signal engineers, but they are men of exceptional ability who have struggled to the uppermost heights of their profession.

To qualify for signal engineering a man should be technically inclined and above all should have a liking for railroad work. There is a lure to the railroads that affects many young men; and if those who feel this calling are at all inclined to be mechanical or electrical, then signal engineering is indeed a pleasant field to work in. A signal engineer spends a large part of his time out of doors and this makes for health and vigor. Good eyesight and color sight are absolutely essential for this work.

At a recent meeting of the Railway Signal Association the present shortage of signal engineers was discussed. During the past few years the railroads have found it utterly impossible to obtain properly trained men to carry on their signal installation and maintenance. This shortage exists at the present time and will continue to exist until enough men are trained in this unique but important branch of engineering. The need for men is growing every day; it must grow as the railroads are extended. The future of signal engineering is only limited by the railroads and there is no need for concern regarding the future of the railroads in this country. Many of the railroads of lesser importance do not have automatic signaling systems at present, but it is only a question of time before this system will be accorded universal adoption. Within the next few years many millions of dollars will be spent for signal equipment.

There is positively no opportunity for a man trained in signal engineering to go into business for himself unless he is able to invest his money in an established signal manufacturing company. There is no need for consulting engineers as each railroad employs its own experts. About the only way a man could get into business would be by inventing a new and practical signaling system and interesting capital in it. There is certainly plenty of room for improvement in signaling devices and a man in this field with inventive talent will have little trouble obtaining reward for any improvements he may devise. The railroads are always willing to pay handsomely for anything that will save life and property.

Considering the nature of the work and the amount of training necessary signal engineers are well paid. Men who have reached the upper regions of this profession find little trouble in obtaining salaries as high as $10,000 per year. From this point the salaries range down to $90 per month for beginners in the work. However, this salary is not any lower than a beginner's salary in any other field. Most of the college graduates in electrical engineering receive from $80 to $100 per month when they start in. The traveling signal man receives about $180 per month and to this is added a certain amount for expenses. Division signal engineers receive from $190 to $200 per month. The salary of an assistant supervisor is about $200 per month with all expenses paid. Supervisors generally receive from $215 to $225 per month exclusive of expenses. General inspectors are paid about $250 per month.

Signal engineers, like all other professional men, should have ambitions and ideals if they wish to progress in their field. Every man in this profession should strive to produce a greater safety of life and property and maintain the system under his jurisdiction in perfect order, which will bring about a minimum of suffering and minimum loss of property through wrecks. The casualties of every railroad depend largely upon the signal system. When signals go wrong, trains go wrong and this usually means a disastrous wreck with its consequent loss of life. Every signal man should be proud to feel that it is within his power to reduce the number of wrecks to a minimum in his position of guardian over the movement of trains on the great railroad systems of our country.

*IT was our recent good fortune to visit and study the switch and signal installation in the Grand Central Terminal. The occasion was when a French reader of the* SCIENTIFIC AMERICAN *was in New York City, as our guest, on a mission of studying manufacturing methods in general and switch and signal mechanisms in particular. Truly, the magnitude of a modern switch and signal installation is wonderful. At the New York Central terminal the trains come and go as though parts of a huge clockwork. In the switch towers the directors, as they are called, follow the movements of trains on an animated miniature of the track layout. Orders are issued by the director to a staff of operators who pull the various levers projecting out from a bank of cabinets. Little green lights indicate the position of any given switch or signal, and whether a track is clear or occupied. An impulse is returned by either switch or signal when its function has been fulfilled, thus conveying positive confirmation to the operator some distance away in the switch tower. Here, indeed, is by no means the least interesting of the many interesting phases of railroading, and Mr. Yates did well to choose this subject for the present instalment of his series dealing with opportunities in many fields.*—THE EDITOR.

### Electrified Milk

AN English scientist, Prof. J. Martin-Beattie, of the University of Liverpool, has made important discoveries in connection with the sterilization of raw milk. The common method in use in America and Europe to make milk safe is pasteurization. Pasteurization is absolutely effective, in that it kills all bacteria, but it can be said that it is not a perfect process, for the reason that it alters the taste of the milk. Pasteurized milk is not "raw" milk. The degree of heat and the mode of its application give pasteurized milk usually a flavor which is objectionable to many.

For several years Dr. Beattie and his associates have been experimenting with electricity as a substitute for pasteurization. They have perfected apparatus for running electric current through milk, and have determined the proper quantity to apply. The application of electricity is of very short duration. It does not raise the temperature of the milk to more than 148 degrees Fahrenheit. The milk is not "cooked," not altered in any essential properties through such heating as is incidental to the process.

# Solving the Labor Problem—III

## How Wages Were More than Adjusted to the Cost of Living, with Increased Output and Freedom from Strikes

By E. W. Hulet, Second Vice-President in Charge of Production, White Motor Co.

THE fact that an industrial concern, employing many thousands of men, has passed through the war and post-war periods without a single strike or any so-called labor trouble whatsoever, is of profound economic significance.

It will not be disputed that a satisfactory adjustment of the relations between the capitalist and labor is the biggest problem confronting the world today. This article is written in the belief that a discussion of the underlying principles and the methods by which the White Motor Company has so successfully solved its own problem under the trying conditions of the past six years, will prove to be of assistance to other establishments that are wrestling with the same problem.

We shall outline the underlying principles upon which our industrial relations system is based, and then pass on to consider the methods by which these principles have been applied.

### The Four Elements in Industrial Relationship

In the management of industry, there are four groups to consider: The stockholder who has money invested; the management who plan and direct; the workman who produces; and the public, which consumes. All four are entitled to and must be given their proper consideration.

Business was originally founded for service, and we are endeavoring to give service with proper relations and in proper proportion. Should any one of the above groups not receive its proper attention, the position of the other three would be jeopardized.

We need capital: the producer and the public will suffer if capital is not given its just return. We need the producer (the management and workmen being considered the "producer"): capital and the consumer will suffer if the producer is not properly considered. And likewise, both capital and producer will suffer if the consumer (the public) is not properly and justly dealt with. This is the old-fashioned principle which we are following.

We feel that our production problem is an industrial-relations problem. Maximum production cannot be had without proper industrial relations, and, with this in mind, we have been working for the past six years to build up a proper relation between management and men. Although in no way perfect, we feel that the better relations have helped to bring about the increase in production which is shown in the accompanying chart.

### Production Is the First Essential

Production is the first essential and of the most importance to industry. Everything must be working smoothly and properly in the factory if you expect production to run regularly, economically, and at its maximum: and to secure production, there must be high morale and the right mental attitude of men to their jobs and to the management, and of the management to the men.

High morale, the right mental attitude of men toward their jobs, means more to production than high speed. High morale has as its basis confidence in management and confidence in the industry. For the past six years our efforts have been directed toward the building of a solid foundation upon which high morale may thrive. We feel that confidence has been established by placing squarely before the employees, through our committees and the *White-Book*, our factory publication, the problems of the management.

**E. W. Hulet, Second Vice-President in charge of Production, White Motor Company, and author of this article**

### The Men Do Not Want to Manage

The workers do not want to manage. It is no part of their scheme of life. They do not want to share the great risks that are run in assuming the responsibility of management. They, the thinking workmen, will tell you that they have not the length and breadth of vision, the training or general knowledge which are necessary to make good managers. The great majority prefer to remain at their own work, for which they have been trained and fitted.

### Contact of Management and Men Through Shop Committees

With a view to bringing about a closer relationship between the management and its employees and to provide a medium through which may be transmitted the thought, feelings, requests and desires from employees to management and from management to employees, we have instituted what is known as "shop committees." Under this arrangement, each department of the works is divided into groups of approximately ten men and a representative is elected by each group. The employees elected by the various groups in one department form the Department Committee. Any employee of the department in which election is held is eligible to act as a committeeman, and the meetings are held biweekly by separate departments on the company's time, and they are so scheduled that only one committee meeting is held at a time. All committees are elected by secret ballot and the committees elect their own chairmen and secretary annually.

The manager and superintendent of the departments represented, with their assistants and general foreman, are privileged to attend the department meetings but are not considered members of the committee. The committee meetings are open forums where all questions of interest, whether pertaining to the factory or not, are freely discussed; questions pertaining to policy, production, expansion and any of the various activities of the factory are debated and graphically illustrated by representatives of the management. Minutes of the meetings and graphic and other charts which have been discussed are posted on the bulletin boards of the department locker rooms for the benefit of the employees.

This very simple form of committee system has been operating successfully in the factory for the past five years. By its means, employees are taught the necessity of production and the proper methods of securing it economically. They are taken fully into the confidence of the management and are given an insight into managerial problems, with every opportunity to follow them up in detail, and, if they so wish, to make suggestions. The "cards are put on the table," and the problems, as they confront the management from time to time, are discussed by a representative of the management at the committee meetings.

Any point deemed of interest may be brought before the committees by members for discussion; and if these are of a nature that would necessitate any great outlay of money or any radical departures from policies and practices, they are referred to the management. If they are considered to be practical and for the good of the industry, they are adopted. When a contrary decision is arrived at, the manager goes before one of the committees, informs them of the fact and discusses the reasons for his judgment.

*I am in a position to state that at no time has the ability of the manager to judge of such matters been questioned by the committees, and that at no time has the management been called upon to bargain with the men collectively for wages, hours or conditions.* The secret of this happy solution of the problem is found in

(*Continued on page 622*)

*AT the recent meeting of the Society of Industrial Engineers, the White Company was held out as a model in industrial relations. There can be no doubt that here is one large corporation that has been able to convince its workers that it is "on the level" in its dealings with them. Were this not the case, it would not have been possible to make the showing recorded in the table mentioned in the text, which we reproduce herewith:*

| Year | Factory Value of Product | Average No. Men | Estimated Buying Power of $1 | Average Weekly Earnings Based on 51 W'ks' Work | Hours Work | Hours Pay | Total Wages | Trucks Per Man Per Year | Factory Value of Trucks Produced Per Man Per Year |
|---|---|---|---|---|---|---|---|---|---|
| 1910 | $ 3,836,290 | 1,072 | | $14.04 | 60 | 60 | $ 767,496 | 2.290 | $3,578.63 |
| 1911 | 5,097,523 | 1,419 | | 12.82 | 59 | 60¼ | 927,696 | 1.985 | 3,592.33 |
| 1912 | 6,739,756 | 1,852 | | 13.53 | 59 | 61½ | 1,278,426 | 1.785 | 3,639.17 |
| 1913 | 6,795,196 | 1,964 | | 13.45 | 59 | 61½ | 1,347,064 | 1.785 | 3,459.87 |
| 1914 | 9,023,172 | 2,202 | $1.00 | 15.03 | 59 | 61½ | 1,688,467 | 1.924 | 4,097.72 |
| 1915 | 21,040,078 | 3,758 | .90 | 16.51 | 54½ | 59½ | 3,163,857 | 2.460 | 5,598.72 |
| 1916 | 17,053,311 | 3,611 | .86 | 17.34 | 54½ | 59½ | 3,186,921 | 2.082 | 4,722.60 |
| 1917 | 22,448,927 | 4,341 | .72 | 20.94 | 54½ | 59½ | 4,637,105 | 2.040 | 5,171.33 |
| 1918 | 30,952,748 | 4,844 | .55 | 27.07 | 54½ | 59½ | 6,688,051 | 2.720 | 6,389.91 |
| 1919 | 35,525,427 | 5,468 | .50 | 31.73 | 49½ | 52 | 8,849,322 | 2.766 | 6,496.98 |

*The factory value of the products includes merchandise and supplies, labor, power and fuel, maintenance and repairs, factory salaries and general administrative expense, insurance, taxes of all descriptions, plant extension costs and dividends. The average value per truck on this basis is $2,347; the increase in price since 1914 is approximately ten per cent. The White people attribute the showing to the provision of ample capital and plant and the use of sound methods of manufacture, to management, and to the voluntary giving by the men of an honest day's work.*—THE EDITOR.

# The Farm Tractor in 1920

## An Effort to Reconcile Conflicting Views and State the True Rôle of the Mechanical Horse

By Francis Z. Hazlett

A RECENT report of an interview with a man who by virtue of the office he holds should be well posted on all the uses to which the internal combustion engine is being put, contained the statement: "Tractors and other gas engines have almost entirely replaced other methods on the farm." This man was probably city-born and bred—possibly one who never in his life stayed on a farm overnight. But if he will take the trouble to look over into the fields next time he takes a drive in his auto, or if he will look out of the window for a few minutes while passing through the rural districts next time he takes a trip on the train, he will very likely see quite a lot of "other methods."

Only a few days later another man, who likewise ought to be up to the minute on farming methods and the needs of farmers, told me that in his opinion there are just three reasons why a farmer should own a tractor. He said: "In the first place, if you own a tractor, your neighbors and the people you know in town will consider you a progressive and up-to-date farmer. Second, if you buy a tractor you can keep the boy on the farm one year longer. He will stay with you the year the tractor is new, but will leave the next year. Third, a tractor may enable you to get your plowing done a little more quickly."

Which man was the farthest astray in his remarks? Ask the next dozen people you see who have given any thought to the subject and the chances are you will have a dozen more different opinions on what the tractor has done and can do for the farmers. You will find the man who thinks that inventive genius and industry by providing the tractor have rescued the farmer from endless toil. You will find the man who classes the tractor with the time-honored gold brick and bogus mining stock—just another means of getting his hard-earned money away from the simple tiller of the soil. You will find the man who cannot understand why the cheap and efficient tractor has not lowered the cost of food. Then there is the man who intends to buy a big tract of cheap land and a fleet of tractors and retire on his first year's earnings; the man who says a tractor may be all right for a rich fellow who keeps a farm to spend his money on; the one who thinks that farm tractors won the war; and the one who considers that the tractor is still in the experimental stage, like commercial airplaning or wireless telephony or colored movies.

Gas tractors first came into general use ten or twelve years ago in the northern part of the Great Plains. Great areas of new land were being opened up for settlement and millions of acres of prairie were being put into crops. Horses were scarce and high priced in this territory, little feed was available, and plowing virgin prairie with them was tedious work.

The gas tractors which were then being made were capable of pulling from six to a dozen plows and offered a means of putting this land under cultivation at a rapid rate. The returns from a large acreage of wheat or flax were so great that the farmers were willing to invest a considerable amount of capital in an effort to make a winning, and thousands of them borrowed money with which to buy tractors. However, the machines were crude, the owners often knew little or nothing about keeping them in repair, they were almost invariably overloaded, some of the manufacturers made little effort to supply the users with repairs and as a result many of these tractors which had been bought at great expense were sent to the junk heap. Most of the owners were convinced that the tractor was unprofitable for farm work, and such of them as were not broke or entirely disgusted with farming went back to doing their work with horses.

These first gas tractors resembled the tractors of today just about as much as the first "horseless carriage" resembles the 1920 automobile. Apparently 1905 is the year when a gas tractor designed to furnish power for plowing was first placed on the market. This machine had a double-cylinder engine, used gasoline for fuel and oil for cooling. It was rated at 22 nominal and 40 actual brake horse-power, and was capable of pulling six to eight 12-inch plows, depending on the soil. It was built to look as much as possible like a steam tractor engine and it weighed 9½ tons.

This was just at the time when automobiles and motor trucks were getting their start and manufacturing circles were alive to the possibilities attending the development of a successful farm tractor. By 1909 there were forty or fifty firms and individuals making or attempting to make tractors. Naturally many of these machines were mere makeshifts, for the manufacturers recognized the advantages of getting in on the ground floor of an industry in the making. At best they were heavy, rough affairs, put on the market without a thorough trial by the manufacturers, and when they were tried by farmers they were found wanting in many respects. Buyers of these early tractors found them unprofitable and unreliable, and the whole idea of mechanical power for farm work was given a serious set-back in the minds of farmers.

Manufacturers realized that if the industry was to prosper better machines would have to be built; that they would have to be capable of doing something besides plowing; and that they must be adapted to a

*Left:* An abandoned tractor on a wheat farm near Salina, Kan. Salvage values appear to mean as little to the tractor farmer as they did to his horse-using predecessor. *Right:* A ten-twenty horse-power tractor running a separator on an Iowa farm

**Two tractors of widely divergent model, and the divergent fates that awaited them**

wider range of conditions than those which obtained in the bonanza wheat fields of the Great Plains.

It was apparent that these first tractors were too large to be used anywhere except on the big level farms of the prairies, and consequently small machines were built. Today, a large percentage of the tractors being manufactured are designed to pull either 2, 3 or 4 plows. There are probably more two and three-plow tractors in use now than all other sizes combined. From the rough machines of poor design, with crude engines, excessive weight, cast gears and exposed working parts, have been developed compact, well-designed machines with cut and hardened gears, efficient driving mechanisms, radiator cooling systems, enclosed and lubricated working parts, kerosene carburetors and air cleaners. The modern tractor can be handled by one man and is light enough and versatile enough to be used for a great variety of farm work. It is invariably equipped with a belt pulley and is used for all kinds of belt work. There are now at least 100 firms actually engaged in the manufacture of tractors and probably twice that many more who are planning to begin in the near future.

The manufacturers endeavor in every way possible to insure that the purchaser of a tractor will be successful with it. Every year the progressive manufacturer holds tractor schools in all the places where his machines are used in any number. Owners of his machines and in fact anyone who is interested can attend these schools, which may last from two days to two weeks, and learn from experts how to operate and care for the tractor. Most of the State colleges of agriculture give similar short courses in "tractioneering." But even with these great advances, farmers have not "taken to" tractors to the extent which many people profess to believe.

There can be no doubt but that the tractor is a boon to thousands of farmers in these days of scarce, poor and high-priced help, but it is only beginning to make its influence felt on farming in general. When we entered the World War there were probably not more than 40,000 tractors in use in the whole country, and there are more than six million farms—only one tractor for every 150 farms. The number has increased until there were probably 350,000 machines used on this year's crops.

There are some tractors in every State in the Union, but just how many there are in each State and just what kind of farms they are on, no one will know exactly until the returns of the Agricultural Census are completed.

Illinois is generally purported to have more tractors than any other State, but the census may put Iowa, Kansas, South Dakota or Nebraska in the lead. The Kansas State Board of Agriculture has collected data showing the number of tractors in use in the State during each of the past five years. In 1915 there were 2,493 tractors; in 1916, 3,932; in 1917, 4,504; in 1918, 5,415; and in 1919 there were 8,609.

There are eight to ten times as many tractors in the whole country now as there were three years ago, but the ownership of a tractor is still the exception rather than the rule among farmers. And as yet very few farmers agree with the enthusiast who sees a tractor on every farm within the next five years and who imagines that all farm work could be done better, more quickly and more economically with mechanical power than in any other way. On the other hand we would have a hard time finding a real live farmer who concurs exactly with my friend and his "just three reasons." The use of tractors will certainly continue to increase, but the farmer, instead of having been anxiously awaiting a mechancal power plant, must, like any other business man, be convinced that something better than his old method has been produced.

The farmer took to the automobile just as readily as did the city man when he was convinced that it would meet his needs, and today there are more automobiles per capita among the rural population than there are in the cities. Similarly, farmers are buying tractors just as fast as they are being convinced that tractors are needed in their business. It is said that more than half the farms in the country are less than 100 acres in size, and probably 90 per cent of the tractors now in use are on farms larger than this. The principal advantage of a tractor is in saving man labor and in doing work which could not be done by other methods. If the man on the small farm can do most of his work himself and can get it done in good season by using the old methods, it is difficult for him to see how a tractor costing from $1,000 to $2,000 would be a paying investment. Except for the saving in man labor, the cost of doing field work with a tractor is probably no less than that of doing it with horses, and on these small farms it will usually be cheaper to hire belt work, such as thrashing and silo-filling, done than to own a tractor and machinery for doing it. It seems now that unless conditions change radically these small farmers, if they expect to use mechanical power economically, must purchase tractors coöperatively, and make each tractor do the work on two or three farms.

The operators of larger farms where there is plenty of work to make tractors profitable quite generally realize the advantages of the tractor, and the only thing which has kept many of them from adding these machines to their farm equipment is that all their ready money has been needed in other places. With the high price and scarcity of farm help, however, many are being practically compelled to buy tractors in order to get their crops planted.

Some are not yet convinced that tractors are reliable, and there are some who do not think themselves capable of operating a tractor successfully. Still others on account of sentiment or ultra-conservatism do not like mechanical power at all and predict the disappearance of tractors from our farms. It is probable that many such men, even though their farms are well suited to the use of tractors, will never own them. Advocates of this belief point out that the tractor, producing no manure and consuming something of which the farmer can grow no part, must revolutionize the entire economics of farming if it is to succeed. Then they assume that this revolution cannot be effected, and argue that therefore the tractor must fail.

As a general rule the tractor is used to supplement the horse-power already on the farm and most farmers who own tractors still keep a part of their horses. Investigations by the Department of Agriculture and the State Colleges of Agriculture show that farmers who now own tractors have not disposed of more than 20 or 25 per cent of their horses on the average. A survey by the Federal Office of Farm Management of corn-belt farms where tractors are owned showed that on most of the farms horses still do a larger percentage of the work than tractors. If a tractor enables a farmer to get his rush work done in better time, of if it makes him independent of hired help or enables him to enlarge his farm, he usually finds that it is a profitable investment, even though he still keeps horses for work to which the tractor is unadapted.

Another typical case where the tractor can hardly compete with the horse is found on the one-man cotton farm. Here the peak of the season's work is not encountered at plowing time at all, but rather at harvesting time. The tractor cannot be used in picking the cotton, and the farmer can plant and cultivate with a horse as much cotton as he can ever pick. So why should he buy a tractor?

According to the reports of the Bureau of Crop Estimates there were still 26,100,000 head of horses and mules on farms at the beginning of the present year. While there was a decrease of 359,000 head during 1919, this represents only about two head for each tractor which was purchased during the year. It must be remembered, however, that the entire reduction is not due to the increased use of tractors. Automobiles and motor trucks are also factors in horse displacement. At least 50,000 farmers have added motor trucks to their equipment during the last three or four years, and the number who own automobiles has been estimated at more than 2,000,000.

# Our Diamond Industry

## How the United States Has Become the Greatest Buyer of Diamonds in the World

By Harry A. Mount

AMERICA is the greatest diamond-consuming nation in the world. Not only do we buy more diamonds than any other people, but we buy the finest diamonds the world's markets afford. It is not surprising, then, that around this traffic has grown a curious miniature industry, whose product is of national importance.

Our diamond industry centers in New York, principally because diamonds and workmen alike have been imported through this port. There is in New York a distinct "diamond district," just above the city's famous financial district. Hundreds of firms and thousands of individual dealers have their offices in this district, and here also are most of the important diamond-cutting plants. Nearly every diamond in this country has passed through the hands of dealers and workmen in this "diamond district."

The diamond district has taken on some of the airs of its neighbor, the financial district, for there are not only brokers, large and small, but a full-fledged curb market where the lesser tradesmen barter among themselves.

Every building in the vicinity of Maiden Lane, John and Nassau Streets has its share of diamond dealers, diamond brokers, diamond cutters, and setters. One skyscraper building is occupied exclusively by diamond interests and diamond jewelry manufacturers.

The curb market, perhaps the most picturesque feature of the diamond district, is at the corner of John and Nassau Streets, where at any time of the year and at any time of the day a group of a hundred or more men can be found standing about, apparently idling away their time, occasionally examining a paper of diamonds under a jeweler's glass. These men are all recognized diamond merchants and deal chiefly among themselves. Many of them have made a section of this curb their office for thirty years or more. While it is impossible to obtain any figures on the amount of business transacted on the curb it is estimated at several millions a year. And this represents just the "tag ends" of the total business done in the diamond district.

Once all the diamonds imported into this country were cut in Holland or Belgium. Fifty years ago a Hollander named Hermann opened a diamond-cutting establishment in New York, but he did only repair work and recutting. There was another small establishment in Boston. From these small beginnings the cutting industry has grown in this country until about a thousand men are now engaged at it and they cut a good portion of the large stones sold here. Because of the high wages paid, however, nothing but stones of considerable value, where the cutting cost is comparatively small, are cut here. But the workmen are the finest in the world, and it is not infrequent that a fine stone already cut in Europe is recut here because of the superior workmanship.

The whole diamond industry is so intertwined with European connections that it is well to recall here, briefly, the system which controls the world's diamond trade.

It is a well-known fact that the mines of South Africa supply nearly all of the diamonds of commerce. India was once the chief source of supply and a few still come from there. A few diamonds are found in Brazil, but there are not sufficient numbers of diamonds found outside of Africa to influence the market. The South African production is controlled by a British syndicate, which thus controls 90 per cent of the world's production, and this syndicate, please take note, carefully manipulates the supply so that it is always a little in arrears of the demand.

It is a rarely accorded privilege to be able to buy direct from the syndicate. Once a buyer is on the syndicate's "list" all he can do is to apply for a "shipment" and await his turn to buy. He is required to fill out an application blank setting forth exactly the character of the goods he wants. He is finally notified that a "sight" of the diamonds will be ready for him on a certain date. It is his privilege, then, to inspect the diamonds and refuse them if he likes. But the privilege of a "sight" is very rarely exercised. If a man rejects a shipment he is penalized by being skipped once or twice when his turn again comes around, or may even be removed from the list. Experienced buyers always take what the syndicate selects for them. Diamonds are apportioned to the different sections of the world according to local demand for color, perfection, size and the like, and since America demands the best qualities the mines produce her buyers usually get the best.

Now most of the buyers on the syndicate's list were formerly in Amsterdam or Antwerp, and in establishing an American cutting industry some difficulty was encountered, not only in finding competent workmen, but in getting buyers "on the list." The process of

## How a Little Ingenuity Retrieved a Broken Drill Set

WHILE drilling a well in granite at a depth of 70 feet, the drill bit broke. The hole was 5¾ inches in diameter and the recovery of the broken bit—a portion measuring about five inches—presented quite a problem. After several attempts a piece of iron was forged with malleable prongs and fastened to a steel rope. The malleable prongs were driven down with such force that they were bent entirely around the broken bit, and raising the prongs and bit to the surface was quite a simple task.—By *R. Franklin Mundorff.*

## Rails Tested by Magnetic Analysis

THE new method of testing steel by magnetic analysis possesses advantages which render it interesting, as a non-destructive means of testing, to supplement tests already in use. Magnetic analysis enables one to detect structural changes due to heating or cooling, or as an indication of mechanical properties; for the mechanical properties of steel are functions of its chemical composition and of its micro-structural and mechanical conditions. The micro-structure and mechanical conditions with regard to internal strains are determined by the heat treatment and the amount and kind of work to which the piece has been subjected. The magnetic properties of steel are also functions of the same variables, and any change produced in one set of properties is accompanied by a corresponding change in the other. The magnetic laboratory of the U. S. Bureau of Standards has developed a method for determining the degree of magnetic uniformity along the length of specimen of substantially uniform cross-section, the method being particularly applicable to steel rails. The test consists in surrounding the rail with a magnetizing solenoid, which is run along the rail. A sensitive electrical instrument, which is connected to a test coil carried with the solenoid, indicates any change in magnetic permeability as the coil is moved along. A method is being developed for testing ball-bearing races on these lines, and experience already gained has furnished sufficient evidence to warrant the conclusion that magnetic methods may be used to advantage in fundamental investigation and for non-destructive testing of steel products. To apply the magnetic test to a forging before machining might save the labor of machining a defective forging.

## A Radiator Flap that Unrolls Itself

THE motor car driver can now sit in his car and adjust the radiator cover flap without getting out. This new accessory is so made that it rolls itself when the driver pulls a string. When the control cord is pulled the flap unrolls upwardly. When let out it rolls itself at the bottom of the radiator shutters. The explanation for this is that highly tempered steel springs are made into the flap itself. On the dash of the cord is a cord holder, and a cord guide which guides the cord as it is pulled.—By *K. H. Hamilton.*

## James Means, Aviation Pioneer

THERE died in Boston on December 3rd James Means, who was largely responsible for the interest of the Wrights in flying. He founded and for several years in the 90's published the *Aeronautical Annual*, in which he made it his business to set forth his ideas with regard to the possibilities of aviation. A regular contributor to his columns was Langley; and it was through their reading of Means' publication that the Wright brothers, according to a speech by Orville in Boston in 1916, were drawn into the design and construction of planes.

## Musical Pitchforks in South Africa

A TALE comes out of England which illustrates admirably the sort of unexpected demand which may have to be met in building up a foreign trade. A British manufacturer of edge tools made up his mind to secure a share of the trade in Kaffir picks, and obtained a sample of the native-made pick, which he reproduced so exactly that it seemed to be impossible to detect the difference between it and the native article. His tools, however, did not sell, and a representative was sent out to investigate. He found there was one thing for which the Kaffir used the pick that had not been taken into consideration. The native took it out of its haft and used it as a cattle call, and every Kaffir had found that the British-made pick had not quite the right note. It speaks well for the enterprise of the maker that, having discovered this, he produced a Kaffir pick with the right note and established a trade which, the story goes, he has retained ever since.

## A Leadless Insect Spray

THE recent discovery of a lead substitute for the making of insecticides, as disclosed at the convention of the American Chemical Society in St. Louis, is anticipated as being responsible for the saving of millions of dollars of farm products. Credit for devising a method of preparing a commercial grade of calcium arsenate belongs to the scientists of the Insecticide and Fungicide Board, U. S. Department of Agriculture.

The use of calcium arsenate as a substitute for lead arsenate is a notable contribution to the industry of manufacturing insecticides because of the cheapness of lime as compared with lead oxide. Of course, calcium arsenate cannot be sprayed alone on tender foliage but when combined with sulfides its application in fighting crop pests is effective.

The method of making calcium arsenate from lime and arsenic acid is prescribed as follows by the Insecticide and Fungicide Board: Obtain a good quality of lime, slake the product to as smooth a paste as feasible, for such a procedure not only determines the smoothness of the finished product but the willingness with which the lime and acid react. Apply from 3 to 3½ times as much water, by weight, as lime, and have the water warm. After standing for a while mix thoroughly, then adding twice as much hot water as used for slaking, mixing the products again.

Add the acid, at room temperature, to the lime without delay, stirring the ingredients well. Crush in a disintegrator or grind if advisable. In order to produce 100 pounds of a commercial grade of calcium arsenate it will require approximately 50 pounds of high grade lime to be slaked with 18 gallons of water, and then 45 gallons of a solution containing one pound of arsenic pentoxide ($As_2 O_5$) per gallon.

Preliminary experiments led to the belief that calcium arsenate might be manufactured directly from limestone, instead of from lime, thus eliminating the expense of burning. However, subsequent tests showed that the chemical properties were not such as to make a suitable product. And, furthermore, there seemed to be no advantage in attempting to substitute limestone for lime; hence the process as outlined above is the one recommended by the Department of Agriculture.

The calcium arsenate as a substitute for lead arsenate is capable of yielding excellent results on resisting plants in the warfare to conquer crop pests. The Department of Agriculture enumerated the following as some of the virtues of an effective arsenical spray:

The absence of an excessive quantity of soluble arsenic, which would result in injury to foliage; manufactured in fine particles that it may be evenly distributed over the foliage; light in form when dry, thus affording easy application by dusting; it should suspend well in water, thus permitting of even distribution when administered in the form of a spray; and when sprayed and subsequently dried should cleave to the plants. On this showing it is plain enough that there is no occasion to cling to the established lead-bearing sprays.

## Tapping the Trolley Wire Without Stopping the Trolley Cars

THE accompanying illustration depicts the method employed by the United Railroads of San Francisco in taking current from the trolley wire without the necessity of removing the device each time a trolley car passes.

Current from the usual trolley wire is often used to operate machines such as air compressors, concrete mixers, banks of camps, and so on, and it is important that the machines or equipment be operated continuously. With the old method it was necessary to remove the device each time a street car passed; but with the new device the passing of street cars does not interfere with the taking of current for operating the machines. In other words, the current-tapping member does not interfere with the passage of the trolley wheel.

The device is supported on a column that stands at one side of the track a sufficient distance away to enable a car to pass. From this column the arm extends out to the trolley wire, and is held tight against the upper part of the trolley wire by means of a rope. The device can be set up or taken down in a minute.—By *C. W. Geiger.*

**A trolley-wire tapping device which does not interfere with the passage of the trolley wheels**

Conducted by H. E. HOWE, Chemical Engineer

## Electrical Production of Alloys

IN a paper before the American Electro Chemical Society, Ralph M. Major discussed the electric production of alloys, pointing out that some of the advantages in melting in an electric furnace are as follows: First, a higher temperature is produced than can be obtained in any other furnace and at the same time this may be controlled. This results in a more rapid melting of the charge and the ability to tap superheated metal, thus allowing time to add deoxidizers and giving the impurities a chance to rise into the slag while the metal cools only enough to bring it to the proper pouring temperature. It is recognized that the requirements upon the refractories are extremely hard. Another advantage is that the atmosphere in which the melting takes place is more nearly non-oxidizing, permitting a greater saving of valuable additive materials such as manganese. Finally, a better quality and more nearly perfect homogeneity of product is possible when using an electric furnace than in any other way.

## Case Hardening of Commercial Steels

A CHART has been prepared by H. B. Knowlton for the heat treatment of four types of steel, which should be very useful. The steels covered are carbon, nickel, chrome nickel, and chrome vanadium. The temperatures and directions for quenching, reheating, cooling, etc., are given. The four treatments are divided as follows: Treatment No. 1 gives a steel that is case hard but brittle, with a strong core but not a tough one and it will not stand shock very well. It is the cheapest treatment and should only be used where great toughness is not required. The second treatment produces case hardness somewhat refined. The extreme outside may be brittle and chip off, and while the steel will stand considerable shock without breaking, the core is soft, coarse-grained, and neither strengthened nor toughened.

The third treatment is applicable only where the carbonizing temperature is accurately controlled and it may cause bad distortion on some parts. The steel so treated is not liable to chip. The core is strengthened and toughened and the steel will resist shock well. The fourth treatment outlined is the best, causing less distortion than No. 3 and is recommended where maximum hardness, strength, and toughness are necessary. The steel is not liable to chip, will stand shock well and has a core both strengthened and toughened. An example of this fourth treatment may be given for carbon steel having carbon .15 to .25. Carbonize 1,600° to 1,700°F., cool in boxes, reheat to 1,600°F., quench in oil, reheat to 1,400°F. and quench in water or reheat to 1,440°F. and quench in oil. The temperatures of carbonizing given assume that a first-class compound will be used and all reheating should be done in lead pots, salt pots, or in small furnaces where the temperatures can be accurately controlled.

## Natural Purple Dye

IN the *Color Trade Journal* for May, it is noted that a shell-fish exists on the Pacific coast of Costa Rica from which an especially fine purple color is obtained and used for the dyeing of silk thread. It is probable that this is the same dyestuff used by the ancients under the name Tyrian Purple, which has been discussed previously in these columns. The method of obtaining the coloring material differs from that employed along the Mediterranean, for it is stated that in Costa Rica the person who picks up the shell-fish merely blows his breath over it whereupon a few drops of greenish liquor ooze out. The silk thread when passed through this liquor and subsequently exposed to sunlight takes on a fast beautiful color without further treatment.

## The Uses of Boric Acid

BORIC acid and sodium tetraborate, the chemical name of ordinary borax, are the most important derivatives of the element boron. The largest use for borax is in making enamel coatings for wire and steel ware. It also finds large application in the glass industry, in the laundry, and the kitchen. It is a convenient water softener and is sometimes found in starches designed to give a high gloss. It is used as a coating for book paper and playing cards, and, as a solvent for shellac, finds extensive application in the hat trade. In tanning, both borax and boric acid are used for cleaning hides and dressing the leather. In the textile industry borax assists in dyeing, and in some parts of the world boric acid is still employed in the preservation of foods. It is permitted in the salting of fish because such foods are soaked in water before cooking and most of the boric acid removed. Being an antiseptic, boric acid is employed for external washes and it finds a place in cosmetics. It is used as a larvacide where it is recommended for the destruction of fly larvæ in manures, for it destroys the larva without affecting the bacteria which increase the fertilizer value of the manure. Finally, borax is a well-known flux used in metal working.

## Synthetic Rubber

THE methods employed in Germany for the production of synthetic rubber had been fairly well known for some time previous to the war, when the comparatively low price of natural rubber—a little over 70 cents per pound—made it unprofitable to compete with it. During the war, when price was not a consideration, the industry was expanded, the raw materials being acetone and aluminum. Acetone was secured from acetylene by a process similar to that employed at Shawinigan Falls. However, synthetic rubber could not be vulcanized and therefore was useful only as hard rubber. The natural rubber was mixed with synthetic rubber in order to produce the soft material needed for so many important purposes.

## Cooking Oils

FAT used for deep frying must have a high smoking temperature and the smoke when produced must not be irritating to the eyes or nose and must increase slowly as the temperature is raised. While standardized methods for determining these characteristics have not been provided, some of the results published indicate that the hydrogenated vegetable oils as a rule have a higher smoking temperature than animal fats. The smoking temperature is believed to be the temperature of decomposition, and if this is true the animal fats decompose more readily and extensively than do the hydrogenated vegetable oils, becoming rancid earlier and not capable of being used so long. Nearly all the fats and oils used in the kitchen have smoking temperatures near 200°C.

## Analysis of Sole Leather

IN *Le Cuir* there is a discussion of the analysis of sole leather with the determination of the water soluble material by the English and French methods. It seems that all physical properties yield data valuable in determining the grade of such leather, including resistance to cutting, compactness of fibers, the color of the cross section, and even the odor, taste, and color. There is apparent need for uniformity in methods, since the two under discussion gave decidedly different results, the English giving the higher values. By this method a sample is first cut and then ground in a suitable mill. Grease is removed from a 25-gram sample by extracting for 6 hours with petroleum ether boiling between 40 and 60 degrees. The solvent is then allowed to evaporate, the leather being spread on a plate in a warm place over night. It is then placed in a Procter extractor, covered with water, and allowed to stand over night, and the next day is heated to 45 degrees at a rate to produce 1 liter of extract in 3 hours. The extract is now filtered through good paper, the first 200 cc. being rejected, and 50 cc. of the clear filtrate evaporated to dryness in a water bath, dried in a vacuum oven, and weighed.

## Cottonseed Meal as a Human Food

IN the *Cotton Oil Press* for May, J. E. Halligan discusses the possibility of cottonseed meal as a source of human food. Since 1905 the meal has been used to a limited extent as a human food in Texas, where the meal has been specially prepared by eliminating the hulls and then grinding the meat to a fine powder. When properly prepared, the flour has a bright yellow color, a sweetish taste, and an agreeable odor similar to that of nuts. If the meal has been extracted and all traces of the solvent removed it is somewhat more attractive.

The high protein content, 43 per cent in meal and 50 per cent in cottonseed flour, at once suggests the possibility of using such meal as a meat substitute. This should interest those who find meat somewhat too expensive, since it is a question whether certain classes of workers now eat enough meat at present prices to satisfy their body requirements for protein. According to some of the authorities, 125 grams of protein are required per day for moderate work by the adult man, yet in some families in our cities this is known to fall as low as 80 grams per day, while in other countries statistics show an even smaller consumption.

Another consideration in favor of cottonseed meal and flour is the ease with which it can be kept indefinitely in dry storage in perfect condition without refrigeration. The bakeries have shown that cottonseed flour and meal may be used in nearly all products ordinarily made from other flours, though the products are richer in protein and fat since cottonseed flour contains five times the protein and ten times the fat of wheat flour, and six times as much protein and four times as much fat as cornmeal. Of course, cottonseed meal products may not agree with some individuals, but this is also true of other foods and every man must learn from his own experience the foods which best agree with him. It would seem that under present economic conditions there would be many interested in at least trying this source of the protein, fat, and mineral elements in the diet.

## Edible Lactic Acid

UNTIL recently edible lactic acid was not an article of commerce because no way had been found to produce it in competition with inexpensive citric and tartaric acid. Today refined edible lactic acid, 56 per cent by volume and 50 per cent by weight, sells around 35 cents a pound; whereas, citric is $1 and tartaric acid about 80 cents.

Within a year this edible lactic acid has been introduced in large quantities to beverage manufacturers, it having been found that the addition of a small quantity to beers of very low alcohol content greatly improves them by combining with the amides and amino acids which are present. As an acid for most of the soft drinks it is gradually replacing citric and tartaric acids, where 1¾ pounds replace 1 pound of citric crystals and 1½ pounds replace 1 pound of tartaric acid. Such lactic acid also finds use in the baking industry, in candy, production of jellies, and in the canning industry where the use of a small percentage of acid of this type facilitates the preservation of meats and fish.

## Our Sugar Supply

SO long as sugar remains difficult to get even at prices that seem unreasonable to us, we can find much of interest in the subject. The sources of supply for the United States during 1919 were as follows:

| | Tons |
|---|---|
| Cuban cane | 2,067,051 |
| From the beet crop of the United States | 872,253 |
| From Hawaii | 514,824 |
| Porto Rico | 286,880 |
| Louisiana and Texas | 154,034 |
| The Philippines | 72,511 |
| St. Croix | 8,286 |

and from maple and sugars from molasses, 34,094 tons. Full duty-paying foreign sugar from miscellaneous sources supplied 57,738 tons, making a grand total of 4,067,671 tons.

This consumption is the highest recorded for any country. Whereas, our great grandfathers consumed about 8 pounds per capita yearly, we reached 85 pounds last year, having gradually increased to that amount from 23 pounds in 1850. It is estimated that in 1920 the consumption for all purposes in the United States will average 90 pounds per capita.

Two statistical items will indicate another cause for the shortage. In 1914 the world's crop was estimated at 19,000,000 tons, of which 9,000,000 tons were derived from sugar beets. In 1919 the total production was 16,000,000 tons, of which only 4,000,000 tons were from beets. The chemist is doing what he can to assist by providing high grade maltose and glucose, but it would seem that we can expect little relief until the beet fields of Europe again become productive after their recovery from the war.

# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*

**Special body designed for the effective handling of plate glass**

## Special Truck Body for Plate Glass Transportation

LARGE sheets of plate glass for modern store fronts are believed to be one of the most fragile of commodities now hauled successfully by motor truck. The adaptation of the motor truck to glass carrying is a problem that has long puzzled body builders as the main difficulty has been in the construction of a satisfactory body to get the floor low enough without underslinging the frame. Manufacturers of plate glass who have tried the underslinging methods state that it has many draw-backs. A Chicago dealer in plate glass has worked out a successful glass carrying truck body that has been mounted on a standard truck chassis and which is shown in the accompanying illustration. It is stated that this body has met every requirement exacted by the great bulk, awkward shape and extreme fragility of plate glass. The height of the floor from the ground is just the normal

(*Continued on page 624*)

## Sand Boxes For Trucks

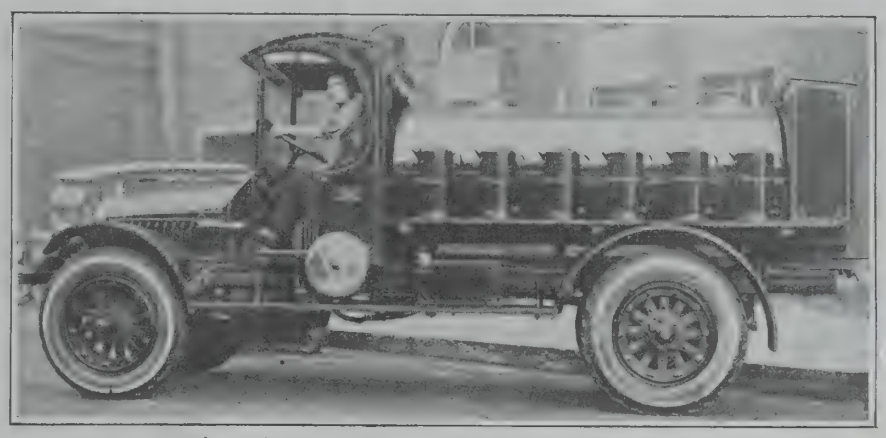
IT is not always possible to operate a truck fitted with traction devices as in some cities regulations have been passed prohibiting the use of any device that may damage the paving of the streets. When the highways are covered with snow and ice the devices can be used advantageously and without breaking the law because they do not come in direct contact with the pavement. There are many conditions, however, where traction is not good and yet the conditions are not severe enough to warrant the use of special traction grips, non-skid chains and similar devices. One of the important adjuncts to trolley cars and railway locomotives is the sandbox, this making it possible to drop sand on the slippery rails and secure traction until the train or car has started. The sand supply is called upon wherever there is a stretch of slippery rails. The owner of a large moving van has fitted his truck with sand boxes and has found them to be of considerable value when the truck is being operated on slippery streets. The discharge of the sand boxes is immediately in front of each rear wheel and is controlled by the driver. When sand is desired a simple control lever opens four discharge nozzles in each sand box and sand is distributed over the ground for a space corresponding to and slightly greater than the width of the tire. This suggestion should be a valuable one to truck operators as the scheme is effective and may be easily applied to any form of truck using solid rubber tires. The sand is not needed as much on pneumatic tire trucks because the modern cord tires made for truck uses are provided with a special tread which gives good traction under practically all road conditions.

**Sand box arranged at the rear wheel for better traction on wet and icy pavements**

## Mobile Concrete Mixing Plant

THE accompanying photographs show a concrete mixing plant mounted on an automobile truck. This plant was developed by the New York Telephone Company for use in the construction of 6½ miles of 12-duct subway between Union and Passaic, New Jersey, and 2¼ miles of 24-duct subway between Jersey City and Newark, New Jersey. The subways constructed were of multiple duct tile with a concrete foundation and concrete top protection. All manholes were built entirely of concrete. The outfit consists of a power batch concrete mixer mounted on a 7-ton motor truck which was also equipped with two

(*Continued on page 624*)



**A useful supply truck for fire-department use**

## Supply Truck for Fire Department

MENTION has been previously made in these columns of the tendency noted in practically all of our large cities to motorize the fire department and not only to use gasoline-engine propelled apparatus but also to replace steam pumping engines with gasoline motor-operated pumps. The horse-drawn supply wagon of the past with its baskets of coal for the steam pumping engine is now replaced by a special truck carrying the liquid fuel and lubricating oil so necessary to internal combustion engines. A vehicle of this type is shown in the accompanying illustration, this emergency oil and gasoline truck being a recent addition to the Chicago Fire Department. A pneumatic tire truck chassis is equipped with a special tank body having running board on which oil tanks are carried. The main tank has a capacity of over 500 gallons of gasoline, while the auxiliary tanks carry 65 gallons of oil. Suitable measures, funnels, tank-filling hose and other tools are carried in a special locker at the rear end of the truck. According to fire department statistics the average consumption of gasoline at a big fire is about 100 gallons, so it will be evident that an effective fuel-supply truck is an adjunct of decided utility. The truck can also be used in making the rounds of the various fire stations to make sure that the tanks of the apparatus are kept filled with lubricating oil and gasoline. The use of pneumatic tires enables the truck to make better speed when its services are required and lessens depreciation in routine work.

**The handy welding outfit that goes wherever a truck can go**

## Mobile Welding Outfit

THE system of welding in which an electric arc is used as a source of heat is of great value in making repairs on the boilers and other metal parts of ships. It is not always feasible to have a current supply of the proper value at the end of a wharf or in a dock where the repair work is carried on. In cases of this kind a mobile welding outfit is operated by a New York concern making a specialty of electric welding. The accompanying illustration shows the manner in which this special truck may be run along side of the boat on which the repairs are to be made. The body of the truck carries a special electrical generating set in which an internal combustion engine drives a dynamo giving current of the proper voltage and amperage to be used in welding. The power plant is self-contained and is independent of the truck engine, will operate on gasoline or kerosene and the arc welding machine will supply power enough for two operators. There is also an air compressor mounted on this truck driven by the truck motor which can supply compressed air for the pneumatic hammers and chisels used in preparing parts to be welded and in finishing off the completed weld. Among the remaining equipment can be mentioned two reels carrying 1,500 feet of welding leads, spare tanks for oil and fuel, air receivers and a complete work bench. The truck is electrically lighted and can be used for night work as well as during the day when rush jobs or emergency work must be performed.

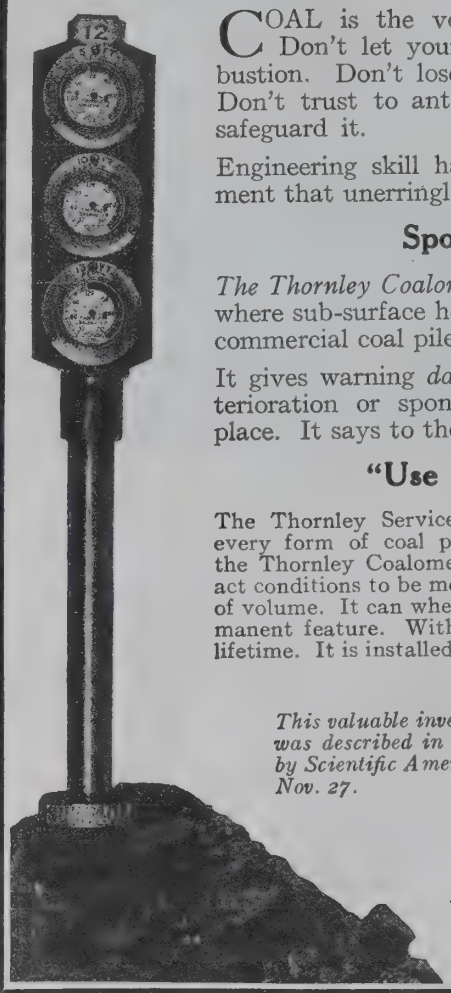
# Protect Your Coal



COAL is the very foundation of production. Don't let yours go up in spontaneous combustion. Don't lose its B.T.U.'s by overheating. Don't trust to antiquated, inefficient methods to safeguard it.

Engineering skill has provided a scientific instrument that unerringly

**Spots Hot Spots**

*The Thornley Coalometer* indicates the precise spot where sub-surface heating is about to begin in any commercial coal pile, bunker, or cargo.

It gives warning *days* before actual danger of deterioration or spontaneous combustion can take place. It says to the watchful engineer

**"Use this coal next"**

The Thornley Service includes special engineering for every form of coal problem. Based on a unit system, the Thornley Coalometer is readily adjustable to the exact conditions to be met in any storage of coal regardless of volume. It can whenever desirable be built in as a permanent feature. With reasonable care it should last a lifetime. It is installed under a five years' guarantee.

*This valuable invention was described in detail by Scientific American, Nov. 27.*

**Thornley Coalometer**

# Recently Patented Inventions

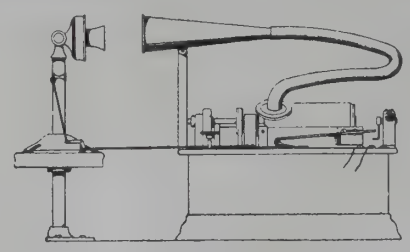
*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc*

### Pertaining to Apparel

GARMENT.—L. T. GOLDBERGER, 395 4th Ave., New York, N. Y. The object of the invention is to provide a garment more especially designed as an outer garment to be worn by children and arranged to permit of readily converting the garment into a bloomer, or romper dress. Another object is to permit of conveniently opening the garment for sanitary purposes without requiring removal of any one of the component parts of the garment.

### Electrical Devices

AUTOMATIC BURGLAR ALARM.—F. A. TERRY, Marshfield, Ore. The invention relates to burglar alarms comprising a telephone set and a phonograph disposed near the set, with brake mechanism for holding a switch hook



A SIDE VIEW OF THE DEVICE

in normal position, a motor, an electric circuit for operating the motor, and completing the talking circuit. An object is to provide an alarm which will send in a call for help over a telephone whenever put into operation by the opening of a window or door.

### Of General Interest

PEN AND PENCIL HOLDER.—C. B. BIRD, 3617 Ellis Ave., Chicago, Ill. An object of the invention is to provide a simple device which may be secured to the clothing and which will hold pens and pencils securely. A further object is to provide a holder which will be held closely to the body of the person upon whose garment it is attached thereby preventing the pens or pencils from working loose from the holder.

LETTER BOX.—F. P. BOAS, 242 Cedar St., Tamaqua, Pa. Among the objects of the invention is to produce a letter box possessing a number of advantageous features; first the provision of a box having a rust-proof exterior, to provide a box having inner and outer relatively movable parts, the provision of means to limit the relative opening movement, to provide a permutation lock, to provide a form of cover to serve as a holder for newspapers or packages, and to provide a means for locking the box to a vertical support.

VANITY CASE.—S. HASLAM, c/o D. Evans & Co., Attleboro, Mass. The invention has for its object to provide a construction of receptacle having a pair of compartments therein, the partition dividing the compartments being secured in the receptacle and providing a hinged support for the receptacle cover, and also supports a catch which engages the cover to hold the latter in closed position.

### Heating and Lighting

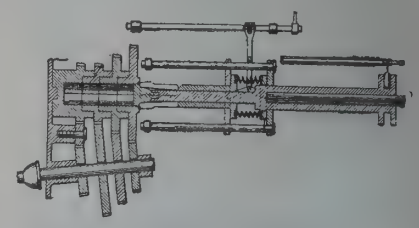
HEATER AND VENTILATOR. — J. A. GREEN, Long Beach Sanitorium, Long Beach, Cal. This invention has for its object to provide mechanism adapted for comfortably heating a room wherein fresh air is taken from the outside, heated and delivered to the room, while the foul air with the products of combustion, is delivered outside the room thus insuring in addition to the heating of the room, a thorough ventilation.

### Machines and Mechanical Devices

MECHANICAL MOVEMENT.—F. CLARK, 120 W. 57th St., New York, N. Y. The invention relates more particularly to a mechanism especially adapted for the conversion of reciprocating motion into oscillating motion. The primary object is to provide a device operated by one of the elevators of a typesetting machine to indicate certain conditions in the work being set up by the machine, the device may be readily attached to machines of this type as commonly constructed.

TIRE TREAD PULLER.—J. SCHMIDT, Box 885, Tracy, Cal. An important object of the invention is to provide a tire tread puller in which the pulley action is so exerted and in which the tire is automatically so positioned during the pulling action that the tread will be completely and cleanly removed from the tire carcass.

VARIABLE SPEED GEARING.—K. K. CLARK, 15 Riverside Ave., Jersey City, N. J. An object of the invention is to provide a gear transmission in which the driving and driven gears are always in mesh and to provide means



A LONGITUDINAL SECTION SHOWING THE SHAFT IN IDLE POSITION

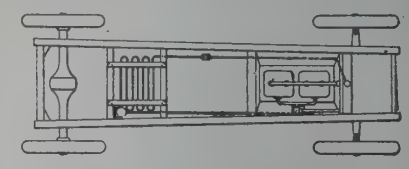
for connecting any of the driving gears with the driving shaft. A further object is to provide means for coupling the drive shaft with any one of the driving gears or position the drive shaft so that it turns idly when not transmitting motion to the gears.

MACHINE FOR COOKING AND DRAINING MATERIAL IN CANS.—A. S. DAVIES, 44 Garfield St., Santa Cruz, Cal. The invention has for its object to provide a machine for cooking and draining material in cans prior to covering and sealing, as for instance fish wherein the cans containing the material are moved continuously during the heating and draining, and are inverted to drain, and finally delivered in upright condition.

TROLLEY.—A. R. WESTERDAHL, Hospital Bay, Cuba. Among the objects of the invention is to provide a link or connecting rod which engages the sheave pins of the trolley and imparts great strength and durability to the structure; a further object is to provide a link which can be placed in position on trolleys as now constructed and which is capable of adjustment to suit the structure on which it is used.

### Pertaining to Vehicles

ANTI-FREEZING DEVICE FOR AUTOMOBILES.—F. WENDLING, 9317 87th St., Edmonton, Alberta, Canada. The invention relates to automobile and other motor cars using water-cooled motors and particularly to anti-freezing devices in connection with the radia-



A TOP PLAN VIEW OF CHASSIS SHOWING CONDENSATION TANK AND CONDENSER COIL AT REAR

tors of such motors, and has for its object the prevention of loss by volatilization of the volatile portions of anti-freezing solutions commonly used. The result is accomplished by an appartus capable of ready attachment to an automobile without interference with the normal operation thereof.

VEHICLE REAR END SIGNAL.—SHIBATARO HARA, deceased, Mrs. Lei Hara, Executrix, Muzquiz, Mexico. Among the principal objects of the invention is to provide a signal apparatus which may be employed in daytime as well as nighttime without adjustment or alteration; to audibly draw attention to the operating condition of the signal, and to provide operating mechanism for the signal, which is simple in construction and readily manipulated.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

**Asbesto-Sponge Felted Insulation**

*The most efficient commercial insulation known. Built up in ply form and therefore not easily damaged by vibration, handling or rehandling—hence its greater economy because of its longer life in service.*

*Efficiencies of*
**JOHNS-MANVILLE ASBESTO-SPONGE FELTED INSULATION ON 5" PIPE**

| *Thickness in Inches* | *Temperature Difference Degrees Fahrenheit* 100° | 200° | 300° | 400° | 500° |
|---|---|---|---|---|---|
| 1" | 83.8% | 86.2% | 88% | 89.8% | 91.2% |
| 2" | 88.6 | 90.3 | 91.6 | 92.8 | 94.1 |
| 3" | 91.1 | 92.5 | 93.5 | 94.5 | 95.4 |

***What Insulation Efficiency Means***

90 per cent efficiency,—for instance,—means that the insulation of that efficiency saves 90 per cent of the heat that would be lost if the insulation were not applied.

***Example:***

One hundred feet of uncovered 5" pipe conveying steam at 150 pounds pressure through a room whose temperature is 70° F. *loses* 1,222,000,000 B. t. u. (units of heat) per year. An insulation 90 per cent efficient *saves* 90 per cent of this loss, or 1,099,800,000 B. t. u. (units of heat).

The equivalents of this *loss* and *saving* in pounds of coal are: LOSS—122,200 lbs., or 61.1 tons coal; SAVING by Insulation—109,980 lbs., or 55 tons coal.

The figures on pounds of coal lost due to uninsulated pipe and saved by use of insulation are based on continuous operation, 24 hours per day, 365 days per year and 10,000 B. t. u. available per pound of coal.

# Low pulse and high fever cost fuel users millions

***How much is lost heat from steam lines costing me?***

**Not long ago fuel users might ask in vain for the answer. Today everyone can know and save fuel through proper insulation correctly applied. Instruments for determining pressures and temperatures; charts and extended calculations are the tools that Johns-Manville Insulation Service is using to answer this very practical business question.**

**Whether you burn fuel in the house, the factory or the power plant, read what the science of insulation has accomplished.**

* * * * * *

Two symptoms always signal heat loss from a steam-pipe. One is lowered pressure in the pipe, the other is high temperature of the air surrounding the bare or poorly insulated pipe.

Now this falling of the pulse and external fever means that fuel in the form of heat is being lost.

It is Insulation's job to minimize this. And so well is this being done by the Johns-Manville Insulation Service that the materials applied are paying for themselves by the heat they save.

### This kind of Heat Conservation has become a science

In past years little was known of the real truths of heat loss. Materials were recommended after inadequate tests; in fact, today if many of the steam pipes covered sometime ago with materials of unknown value were checked up, their covering would be replaced by insulation of known value, and new records for economy set up.

Rising fuel prices make heat losses doubly serious and economy in heat transmission has been realized to be a real factor in cutting heating, power and manufacturing costs.

### Changing the physical design of Insulation

An insulation to be of maximum value must have more than the property of preventing heat loss. It must also have physical durability, for a short-life material means early replacement, so that if insulation values are equal, the most durable insulation is the most economical.

If it is desirable to reduce a loss, it is surely advisable to reduce the loss to a minimum. Believing this, Johns-Manville developed physically strong-felted insulations—and with obvious advantages to the fuel user. For these felted insulations are built up in ply form, physically strong and not easily damaged by vibration, handling or rehandling. These improved materials have not only overcome the physical shortcomings of most insulations, but made higher heat efficiencies possible. In fact, on test, one of these insulations has repeatedly been shown to be the most efficient commercial material in existence.

*To show the great flexibility of felted insulation, so vital to long life. Nothing to break, crack or powder off as in molded materials.*

### Insulation for every service

No one material should or will serve all practical needs. Steam service where high pressures are used demands different treatment than cold water or brine service. Johns-Manville, in realization of this, offer materials suitable for use indoors and out; overhead and underground and for every type of system, and not only does this service include the furnishing of the materials but their application as well.

The application of an insulation is vital to its performance in service, hence the necessity of controlling this factor if economical results are to be obtained.

# JOHNS-MANVILLE
## Serves in Conservation

# Superheat Drills Holes

## *Few "steam metals" can withstand its active chiseling action*

So in great valves that control superheat flow for vital power production, leading designers call for essential working parts of Monel to withstand high speed gas erosion.

For, of all commercial metals, Monel alone has the ability to survive the combined chemical and mechanical attack of superheated steam at the high and rising pressures commonly used today.

In proof of this, Monel is used for guide stems, wedges, seat rings, spindles, dash pots, piston rings, clappers, piston lock nuts, pistons, etc., in the huge control valves built by Jenkins, Pratt & Cady, Crane and others equally prominent.

Monel is standard for service calling for acid, alkali, high heat and steam wear resistance. It has a prominent place in the specifications of such seasoned engineering organizations as J. G. White, Stone and Webster, Dwight P. Robinson Inc.

The name Monel identifies the natural nickel alloy—67% nickel, 28% copper and 5% other metals—produced by The International Nickel Company.

THE INTERNATIONAL NICKEL COMPANY
43 Exchange Place, New York
The International Nickel Company, of Canada, Ltd., Toronto, Ontario

THE larger picture is a "close up" of the clapper and seat ring shown in the broken out part of the small valve illustration. The clapper is seen about to lift in order to allow steam to pass into the line. The irregular spurts of steam show that the seat between clapper and ring is no longer perfect—that superheat has commenced to drill its way through. This drilling action is always in process where superheat is used, and the commonly used metals for valve parts eventually fail and allow superheat to cut through. For that reason Monel is the only safe metal for valve parts that are in constant contact with superheated steam—the only metal that insures always tight valve closure.

INCo Monel metal

THE INTERNATIONAL NICKEL COMPANY

### Radio Prize Winner for 1919

THE Lieut.-Col. Liebermann Memorial Prize, consisting of the interest for 1919 on $10,000 and awarded for the best work of the year in progressive discovery tending toward the advancement of radio, has been awarded to Roy A. Weagant, consulting engineer of the Radio Corporation of America, for his discovery—elimination of static interference.

This prize, founded a year ago by a friend of Lieut.-Col. Liebermann, who was killed in action leading his troops in France on August 8, 1918, was awarded for the first time to Leon F. Fuller, chief engineer of the Federal Telegraph Company a year ago.

Mr. Weagant, honored this year, is a native of Morrisburg, Ontario, Canada. He was educated at Stanstead College and McGill University. He studied physics under Sir Ernest Brotherford and first became interested in wireless through witnessing some of his experiments in Hertzian waves. He took up commercial wireless work in 1908 and in 1912 entered the employ of the Marconi Wireless Telegraph Company of America. He soon rose to the position of chief engineer and when the Radio Corporation of America absorbed the Marconi Company he was retained as consulting engineer.

Mr. Weagant is a fellow of the Institute of Radio Engineers and a former member of its board of directors and standardization committee.

### Power and the City

(*Continued from page 608*)

plants at San Pedro (the harbor district of Los Angeles) were of course founded to meet the stress of war, but their projectors were governed in their choice of a location chiefly by the cheap power supply.

Another great industry, made profitable by cheap power, is the canning of fish, particularly sardines, which abound in the adjacent ocean. Still another is the making of automobile tires. This was, of course, based on the successful growing in Arizona and southern California of the long-staple Egyptian cotton that is so essential to the making of good tires. The company that started Egyptian cotton growing in Arizona in 1918 speedily realized that the abundant water and cheap power of the aqueduct would not only enable it to make tires at Los Angeles for all Pacific coast points but would also enable it to ship them East by water and deliver them to its trade more cheaply than was possible to deliver from its big factory at Akron. Its cotton spinning factory, which alone will operate 33,000 spindles, for which the company expects to import 1,200 skilled women operatives from New England, was scheduled to open in June and the rest of the great tire factory, with 6,300 more operatives, in September. Another tire factory is to break ground immediately.

An industry more recently initiated in southern California is that of making vegetable oils. A company which has been operating a huge plant at Portland, Ore., recently broke ground at San Pedro for a new factory, to which it purposes to transfer its business. Cheap power was the controlling factor.

When the aqueduct was being built an $800,000 plant was built to supply the enormous quantities of cement needed in the work. Since the work was finished this plant has lain idle, its hugeness making it too costly to be successtully operated under competitive conditions. Recently it has been leased by the city to Portland people who are now transforming it into what they say will be the largest commercial potash factory in the world. While the ownership of great deposits of feldspathic rocks in the country southwest of Los Angeles was an inducement to the company to come there, yet it was only the cheap electric power that made it possible to operate at all.

Each of these big industries has its own story—and a fascinating one at that. But the one factor that stands out in all of them is that they located where they did because of the cheapness and abundance of the electrical power of the aqueduct.

Other industries, impracticable without electric power, have been begun in a small way and will probably be rapidly expanded.

Among these is iron making. California, though not popularly known as an iron-producing State, nevertheless has an abundance of low-grade iron ores, which have never been mined because no coking coal for their melting was economically available. The electric furnace, however, does not need coke and is expected soon to turn out enough pig iron to supply the coast's needs for use in the fabrication of products for the local market.

A much more important class of ores, abundant in southern California but up to now capable of being handled economically only at Niagara Falls, is those from which chromium, tungsten, vanadium, molybdenum, manganese and other rare metals can be extracted. All such products, which though not great in tonnage nor volume are of enormous importance in the steel industry, can now be extracted by the electric power of the aqueduct and the prohibitive railroad freights to Niagara Falls eliminated. Again, the copper ores of Arizona and Utah, now shipped to Perth Amboy, N. J., for electrolytic refining, can be refined with a great saving in railroad freights by means of the cheap power of the aqueduct current. Truly, electrical water power is the present-day magician at whose behest factories and cities rise.

The extension of the light and power systems of the aqueduct throughout Los Angeles has not been carried on without strong opposition from at least one of the private electrical supply plants that supplied the city before the aqueduct was built. When the question of an aqueduct was first mooted, the companies in possession of the field naturally opposed the whole project. When overwhelmingly overruled by the people at a special election, they utilized the five years that it took to build the aqueduct in entrenching themselves in the city. Nevertheless, when, in January, 1917, the city began to distribute and sell electrical power its ability to conquer the field was so evident that one of the two companies immediately proposed serious negotiations for the sale to the city of all its transmission lines and business within the city limits. The company's stations were outside the city and much of its service was to extra city customers scattered over an extensive area, and this part of its business it of course wished to retain. Its proposal was so plainly in the public interest both in and outside the city that the municipality at once agreed to it in principle and stopped building distribution lines in the part of the city occupied by this company, pending agreement on details, thus avoiding the economic waste of building parallel lines.

The second lighting company, which occupied a large section of the city, took a different view of the situation and refused to consider negotiating the sale of its business to the city under any conditions. So the city "invaded" its territory by building distribution lines into it. Apparently, the contest was brief and decisive, 75 per cent of the company's customers changing over to the city lines as soon as these were available. Actually, however, the company's lines covered a large part of the urban portion of the city, and the part that had been invaded was comparatively small. It was of course apparent that the city could conquer the company's territory if it cared to continue the invasion on a large scale, but this would involve a heavy economic

## The Hack Saw Chart

Which saw will insure the most economical cutting of any particular material? One has only to consider the multiplicity of factors as represented by the material, the saw and its operation, to realize the difficulties encountered in arriving at the correct solution of this problem.

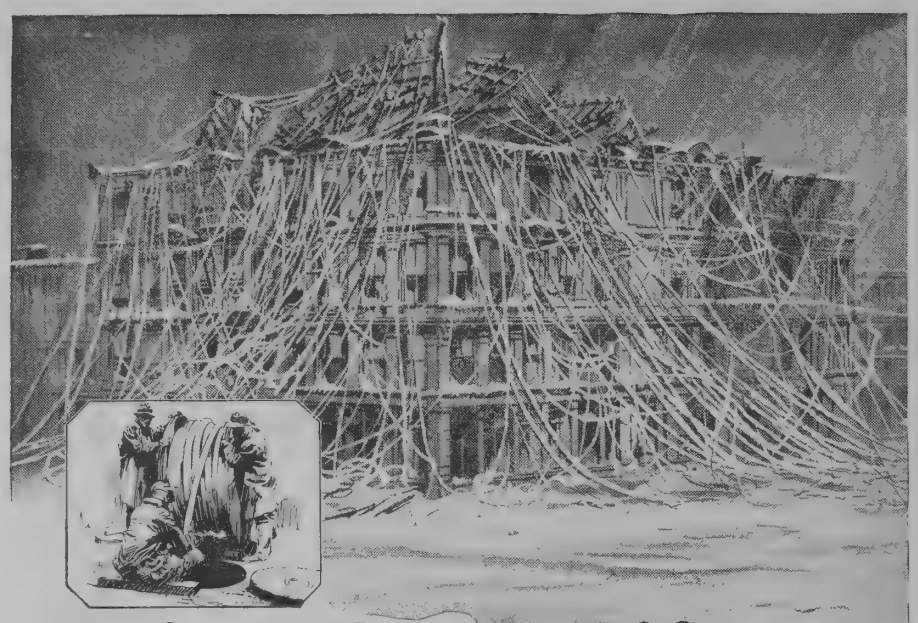
## Necessity Universally Recognized

Practically every saw manufacturer has made some attempt to answer the question. A number have gone no further than to suggest the obvious—that is, that the saw used for cutting brass or sheet metal should have more teeth per inch than that used when cutting steel or round stock. Some, however, go further than this though not necessarily to the extent of conducting careful tests and the compilation of records over a series of years as one or two have done, but yet far enough to recommend with some degree of definiteness, the employment of blades of certain physical characteristics, to cut certain classes and shapes of metal.

## The Practical Solution

One manufacturer—The L. S. Starrett Company—as the result of experiments and tests, has divided materials and shapes into nine such classes, the distinction being based on observation of the influences exerted by the hardness, ductility, crystalline structure and chemical composition of the various metals, and the diameter and shape of the material to be cut. For these different classes of materials, different blades have been designed and manufactured, and the classifications, with the blade recommended for each, have been embodied in the HACK SAW CHART.

In a more elaborate and technical way this Chart might have been made up so as to show the composition and temper of each blade, but for the fact that saw numbers on the chart supply all necessary information where saws of this make are employed.—From *Hack Saws and Their Use*, published by The L. S. Starrett Co., Athol, Mass., for free distribution. A copy of the Starrett chart will be sent free upon request.



# The Contributions of Science

The greatest material benefits the world has received have come from the laboratories of the scientists. They create the means for accomplishing the seemingly impossible.

Science, after years of labor, produced the telephone. From a feeble instrument capable of carrying speech but a few feet, science continued its work until now the telephone-voice may be heard across the continent.

In February of 1881 a blizzard swept the city of Boston, tearing from the roof of the Bell telephone building a vast net-work of 2,400 wires. It was the worst wire disaster the Company had sustained.

Now through the advance of science that number of wires would be carried in a single underground cable no larger than a man's wrist.

As the fruit of the effort of science greater safety and greater savings in time, money and materials are constantly resulting.

And never before as now, the scientist is helping us solve our great problems of providing Telephone service that meets the increased demands with greater speed and greater certainty.

loss by the necessity of duplicating the company's lines and would at the best unnecessarily use up money which might better be used in supplying parts of the city that had no electrical service at all.

So the city simply held the part of the area that it had conquered, and for the time being spent its available money elsewhere, notably in building heavy transmission lines to the harbor district, where the municipal docks, cotton compresses, fish canneries, shipbuilding, and other plants wanted the power to supply their growing needs. It also built into an industrial district on the east side where many factories, large and small, were using oil for fuel; this was done at the request of the United States Government, which desired to conserve oil for war and other purposes by substituting hydro-electric power. This resulted in a marked rehabilitation of the district.

The electrical energy at first in actual use was derived from what is known as the San Francisquito power plant No. 1, located on the line of the aqueduct 47 miles northeast of the city, which develops 37,500 horse-power, and from a minor plant which develops 3,000 horse-power and is commonly used to help carry the peak load at the rush hours of the day. Another plant, known as San Francisquito No. 2, located in the same canyon seven miles nearer town, was finished in June and has added two units of 19,000 horse-power each to the existing service. A third unit of 19,000 horse-power unit will be added at this plant later. Two other plants, San Fernando and Franklin Canyon, located much nearer the city, will contribute 14,000 horse-power by Christmas. The same water will successively furnish the power to each and every one of these plants.

All told more than half the total developed and potential power of the aqueduct is practically at the city gates; the rest is more distant and will require longer though by no means unusually long transmission lines.

## Solving the Labor Problem—III

*(Continued from page 611)*

the fact that the management and the men, always having played fair, have come to have confidence in each other.

### Relationship of Wages to the Cost of Living

In formulating our system of industrial relations, naturally the question of wages occupied a leading position. We devoted a great deal of time and study to this subject, going back into history for suggestions and guidance. We found that a comparative study of the trend of the cost of living for many centuries and in many countries, showing the natural effect upon it of various wars, furnished us with a basis for computing the probable trend in America during the period of the late war and subsequent production.

We then drew up plans for a steadily increasing wage scale, designed by automatic periodical advances to keep pace with the increasing cost of living and thereby make it possible for the workmen to maintain a normal standard of living. We are glad to be able to state that up to the present time, this forecast has been fully justified, the average wage having more than doubled, while the purchasing power of the dollar has shrunk by one-half.

In connection with our study of this subject, we found no *satisfactory* system of bonuses, profit sharing, premiums, piece rates or other participation in earnings of any kind, although some of these plans have been adopted and are apparently successful in many other industries.

Our policy is to maintain what we consider to be a just rate of interest on capital stock and then, after making provision for the necessary overhead charges, we share our profits with our employees every two weeks in their pay envelopes.

### How So-called "Welfare Work" Is Handled

In working out a system of so-called "welfare-work" we have realized that to be effective it must not carry with it to the minds of the men any idea of charity or paternalism. This conviction we found to be very strong among the men themselves. They wished that everything that was done in the way of benefit societies, recreational clubs and restaurants should be regarded as services to the employees for which they pay. They believe that the cost of these things is a part of the cost of production. Consequently, the maintenance of these departments stands on the same basis as the maintenance of purchasing, cost, or payroll departments, and the men understand that through their production they are paying for such service. The costs are charted, to show cost of each department on a "per day, per man" basis. These charts are placed before the men with the understanding that, by a two-thirds vote in the factory, any of the service activities, other than those necessary to comply with State requirements, can be discontinued.

There is not space within the limits of this article to describe these welfare activities in detail. There is the factory kitchen and restaurant, which supplies food at a figure slightly below cost; a library to which employees have easy access at all times. The latter is operated as a branch of the main public library, making it possible for a man to order any book from that institution on the card issued by the company's branch. Recreation in the form of athletics forms a large part of these activities and includes a baseball team, basket ball, bowling, football and other clubs.

A very important organization, also managed entirely by the employees, is the Benefit Society, under which, in case of sickness, a member is paid $12 a week for twenty weeks and $10 a week for the next twenty weeks. The death benefit is $500, half of which is donated by the company and the other half paid by the society. Another activity that is exceedingly popular and has proved to be very helpful is the factory publication known as the *White Book*, which is published monthly. It is mailed free of charge and reaches some 20,000 people. Contributions are received from all departments, both in the factory and office, and it serves as a medium of mutual interest and education for management and employees alike. The more serious part is occupied by articles of a technical or educational nature and by editorials which place before the employees all of the company's policies, with full discussions thereof.

### Americanization of Employees

For the benefit of non-citizens employed in the factory—about 20 per cent on January 1, 1919—a course of instruction is given during company time by an educator particularly fitted for this work, the principal object being to enable these employees to get their second papers. On January 1, 1920, after a year of such instruction and assistance, there were but 68 out of 5,826 employees who had not as yet secured their first papers.

### Conclusion

We desire that our people be reasonably contented. We want them to realize that the position of our establishment in industry, and its continued growth offer them their opportunity for development, and practically secures for them their economic status in society. We want them to understand that it is only by the continuous growth of the industry that we are all raised out of our present conditions, and then only through work directed by intelligent management. We give them to understand that we can attain our ideals only by all of us diligently working together for one common end. We are educating our men in the fundamentals of economics, in the bene-

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

**SCIENTIFIC AMERICAN**

Contains Patent Office Notes, Decisions of interest to inventors—and particulars of recently patented inventions.

fits of honest coöperative efforts and in the value of service, not only in industry, but in society and in the home. We believe that this kind of education will bring about a harmonious understanding, on the part of the men, of the policies of the management and the principles upon which they are founded. To show the importance attached to our education, and Industrial Relations, this department is placed at the top of our organization chart, believing that the other functions, namely, engineering, production and manufacturing, no matter how perfect within themselves, can be even more effective when preceded by the proper education.

### Our Diamond Industry

(*Continued from page 614*)

getting "on the list" is a long and tedious one, sometimes requiring fifteen or twenty years of persistent effort on the part of an individual.

And so not only were the diamonds and the workmen imported from Europe, but the buyers of the rough stones had to be imported, too. It is because of this fact that many of the important New York diamond merchants even today are descendants of Dutch families, and can trace a lineage of diamond merchants through a century or more.

It is said that fully 80 per cent of the diamond cutters in New York are Hollanders or the sons of Hollanders, and practically all of them are from families in which every male member is a diamond cutter. These cutters are all members of an international union which controls very closely the apprenticeships to the trade. Until very recently it was practically impossible to learn the trade unless the lucky applicant had some relative already in the union. The union fixes wages, but the wage any individual receives depends upon his skill and speed as a workman. A year ago, when the demand here for diamonds was phenomenal, diamond cutters in New York made from $100 to $150 a week.

Excepting that steam and then electricity have been applied to the diamond cutters' tools to replace foot-power, there has been slight progress in the art since the days of antiquity. The only really important invention to aid the diamond cutter during many centuries of steady activity has been the diamond saw, which has been in use for a number of years. When the rough diamond arrives at the factory each stone is closely examined to determine the weight, flaws, and the direction of the planes of cleavage, which can only be dete mined by an expert. If it is decided that the stone should be divided into two or more pieces, the cleaver cements the diamond to a wooden stick and with another diamond cuts a narrow groove at the exact spot selected. A dull steel knife is inserted in this groove and a smart blow struck upon it. If this has been skilfully done the diamond divides at once and both surfaces are as smooth as if they had been polished. The process requires the greatest skill and care on the part of the cleaver for any error would cause serious loss.

The later method of sawing accomplishes the same result but with less chance of error. Half of the stone is imbedded in a small metal receptacle filled with melted soft metal and the edge of the circular bronze saw is set against it at the point selected. The saw gradually cuts its way through. It may require from three to four days to cut through a large diamond.

After the stone has been cleaved and sawed into the most economical sizes for cutting, the pieces are fastened with a strong adhesive to the demountable spindle of a small lathe. A number of diamonds are similarly mounted. A diamond is screwed on the end of a handle and is used as a tool for cutting the diamond in the lathe, being held against it by the workman. The stone used as a

# What Happens

## When you brush teeth in this way

Five quick effects occur when teeth are brushed in this scientific way.

Millions now get them twice a day. Leading dentists everywhere urge all to get them.

Ask us for this 10-Day Tube. It will show what these effects mean in whiter, cleaner teeth.

### The five effects

Pepsodent multiplies the salivary flow. That is Nature's tooth-protecting agent.

It multiplies the starch digestant in the saliva. That to quickly digest the starch deposits which, if left, form acid.

It multiplies the alkalinity of the saliva. That to neutralize the acids which cause tooth decay.

Two factors directly attack the film on teeth. One keeps the teeth so highly polished that film cannot easily adhere.

These are all desired effects. They are aids to Nature which authorities approve. See how they change your tooth conditions in this ten-day test.

### You are welcome to this test

A 10-day Tube of Pepsodent is sent to all who ask. It is bringing a new dental era, and we want you to know the facts.

### The fight on film

Pepsodent results from many years of effort to fight film on teeth. Film is that viscous coat you feel. It clings to teeth, enters crevices and stays. The ordinary tooth paste does not end it, so film-caused troubles have been constantly increasing.

Film is what discolors, not the teeth. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.

Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea. Thus most tooth troubles are now traced to film.

Now dental science has found ways to fight it. These methods are embodied in Pepsodent. Five years of tests have amply proved it. The highest authorities today endorse its principles. Millions now employ it.

Send the coupon for a 10-Day Tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how teeth whiten as the film-coat disappears.

The book we send explains the reasons for its multiple effects. See and feel them, then judge for yourself how much they mean to you and yours. Cut out the coupon now.

tool is worn away at the same time, and it is manipulated so that both stones are gradually brought to the proper shape. When the stone in the lathe has been finished, the one used as a tool takes its place and another is used as a tool. Thus the diamond is "turned" into a lusterless cone of the usual diamond shape. Then it goes to the polisher.

The polishing takes place on a horizontal disk which revolves at an extremely high rate of speed. The disk is of a close-grained semi-steel which founders in the country have so far been unable to produce. The working surface is impregnated with a mixture of oil and diamond dust and when the stone is held against the revolving disk a flat face or "facet" is gradually ground on it. To secure the greatest brilliancy the stone must be cut according to an exact formula, having a definite number of facets and with precise angles between them. The stone is mounted either in a mechanical holder or at the point of a pyramid of lead and tin composition, while the holder is secured to a short copper rod. By bending this copper rod one way or the other the workman varies the angle of the cut. He is provided with a crude gage for determining the proper angle of the facets; but for the final accuracy he must depend mainly on his eye. Since the brilliancy and value of the stone depend on the accuracy of his eye, it can easily be seen why the polishing of these precious gems is entrusted only to the most expert workmen.

However all that may be, Yankee ingenuity has invaded even the sanctified realm of the diamond polisher. A machine has been invented for regulating automatically the angle of the cut, size of the facet, and number of facets. Still, a majority of gem experts continue to believe the process is not entirely successful, and it seems likely the expert diamond cutter is in no immediate danger of extinction. Each stone, it is argued, ought to be considered as an individual, for there are no two alike. Each should receive a little different treatment to bring out its full value and this can only be done by the expert workman. For this reason the best stones, no doubt, will always be cut by hand.

Recent news dispatches from Berlin bring the statement that at last German scientists have succeeded in making synthetic diamonds which cannot be detected from genuine stones by any of the accepted tests. New York diamond merchants generally disbelieve the statement.

"I do not believe," said a gem expert to the writer, "that it ever will be possible to duplicate a diamond so that an expert cannot detect it. The successful manufacture of synthetic rubies and sapphires has not affected the market for these genuine stones. The genuine stones are selling for a higher price today than ever before, and that in spite of the fact that the synthetic stone is being made better and cheaper every day. Even if synthetic diamonds are achieved—and I doubt if they ever are—I do not believe the market for real diamonds will be in the least affected."

Along with the growth of a diamond industry in this country, and partly because of it, the average American has become "diamond wise." He knows a good stone from a bad one; he can detect a flaw; and he knows a good color.

"Fifty years ago," says the gem expert, "it was only necessary for a jeweler to guarantee that a stone was a genuine diamond to satisfy the customer. Today the customer knows too much about diamonds to be satisfied with any such superficial guarantee. This creates a demand for fine gems which, in turn, is the reason for the existence of an American diamond industry.

"Fifty years ago it was only the leading jeweler of any city who carried diamonds in stock. Today you can see windows full of them on display, even at the cheaper class of stores. The diamond has come to be something of a factor in American life, and I think it has come to stay."

## Special Truck Body for Plate Glass Transportation

(*Continued from page 617*)

height of a man's hand when the arm is extended for effective lifting. Consequently, loading and unloading the truck is much easier than would be the case if the glass sheets were carried higher. The closer to the ground the glass comes, within reasonable limits, the less the chances of trouble due to dropping it. One of the important advantages incorporated in the construction of the body is the fact that the sheets of plate glass are loaded into it in a vertical position instead of being placed horizontally. The advantage of this is that sheets of plate glass of large size can be carried on a body of ordinary width that could not be handled very well if a wide truck body was required, on account of difficulties of maneuvering in traffic. The rack sides of the truck body are provided with special clamping members that hold the plate glass firmly against the packing strips. These clamping members consist of slotted guides having felt pads at the end, which are held in place against the glass by means of substantial wing nuts. The method of using the clamps is clearly shown in the rear view of the truck. The wheel base of the truck is 14 feet and the frame length 16 feet. In order to supplement the easy riding the truck is fitted with special cushion wheels which supply a resiliency greater than that which would be obtained by the ordinary solid tire. It is stated that since the truck has been in service, no matter what size sheet of glass has been carried, not a single piece has been broken in transit.

## Mobile Concrete Mixing Plant

(*Continued from page 617*)

gravity hoppers, one for sand and the other for stone, together with a water tank.

The materials for concrete were assembled at some convenient central location on the job and the stone and sand loaded into the hoppers by a power loader, as shown in one of the photgraphs. Bags of cement were also put on board and at full load the outfit carried material sufficient for five cubic yards of concrete. The power mixer was fed by a laborer on the truck shoveling sand and stone from openings at the bottom of the gravity hoppers and the concrete was poured directly into the trench or manhole excavations by means of a spout. It was found that with a little practice the truck chauffeur could regulate the forward movement of the truck to give the required thickness of concrete in the trench, so that very little hand spreading was necessary. This equipment was developed to meet the conditions existing along the route over which the subway was constructed between Union and Passaic, N. J., where traffic was very heavy, the highway comparatively narrow and bounded on each side by swamps.

To deliver the concrete material along the trench and mix it with a non-automobile mixer would have required platforms in the swamps for the mixer and material about 500 feet apart at a very high cost. The saving by the use of the automobile concrete mixing plant was, therefore, very great. On the Jersey City-Newark run, while it would have been possible to mix concrete in the usual manner at various stations along the trench, the use of the automobile mixer plant was found to be about 25 per cent cheaper than the use of fixed concrete mixing stations and the dumping of concrete into the trench and manhole excavations from wheelbarrows.

# *In the Land of Perpetual Light*

TWILIGHT! That impressive time when the sun goes down behind the hills and calls it "a day." In the city, street lamps blaze forth to show the way, trolley cars become moving houses of light, while one by one the windows of office buildings, stores and homes take on a more cheerful look. In the country, a lone farm house on the hill stands out as a beacon of comfort, and down in the valley a locomotive headlight guides the traveler safely on his journey. The night has come, but light remains, for electricity knows no darkness.

Electric light is no longer a luxury. From Edison's first lamp to the present-day MAZDA, forty years of development have made this element of civilization more and more a necessity. It has made the streets of large cities and small hamlets safer and more attractive. It has blazed the path of the iron horse on land, and has cut a course through fog and mist for giant ships on the high seas. It has saved lives of men who work in the bowels of the earth. It has made motor highways of country trails. It has enabled surgery and medicine to make more rapid strides in correct diagnosis. On the farm, it has brought city comforts, and in the office and factory it has made for better work and happier workers. In short, it has made the world a safer place, a more cheerful place in which to live.

Perhaps the greatest contribution of the General Electric Company to better light has been the development of the MAZDA lamp—but G-E service also includes the research and the initiative necessary to put *the proper light in the proper place*, whether for a tiny flashlight or a huge marine searchlight. G-E engineers have not only developed lamps, they have fostered scientific illumination, and they have created and built the apparatus which has made modern lighting possible, from the harnessing of Nature to generate current, to the safe transmission of this current to the places where perpetual light is desired.

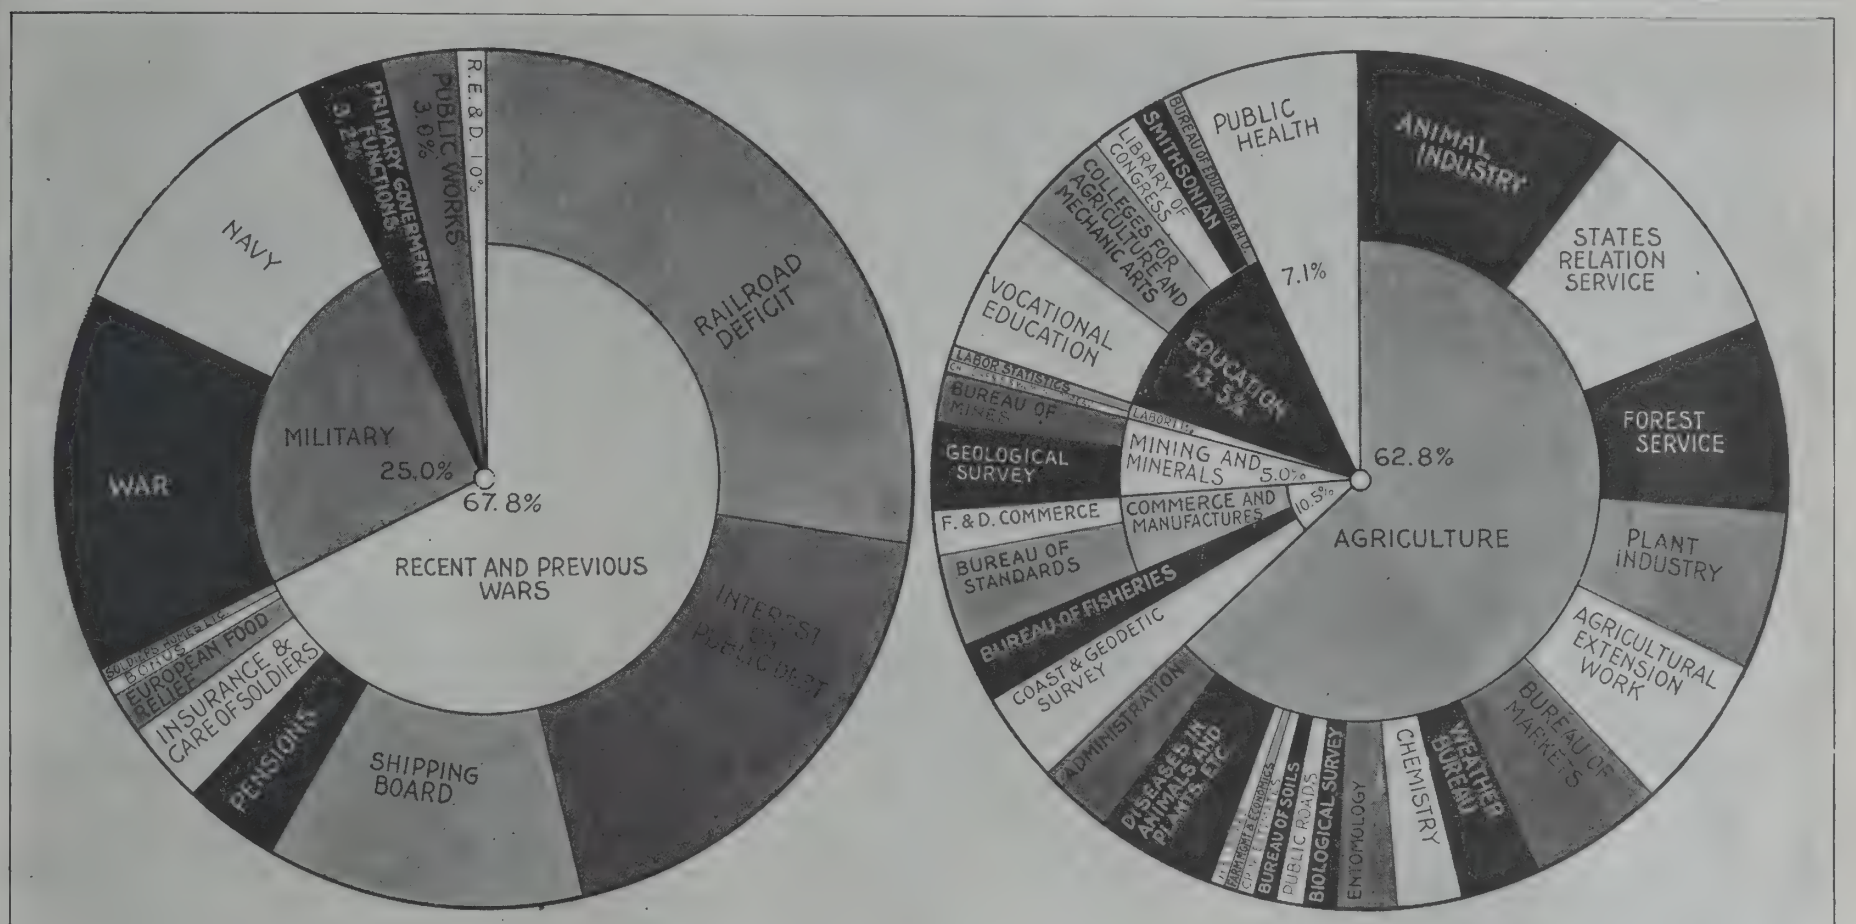
20 CENTS IN CANADA



*Left:* Distribution of the entire Governmental expeditures for the fiscal year 1920. Over 92 per cent goes for war and things connected with war: a bare one per cent for research, education and development—which gets so small a share, in fact, that there is not room to label it in full. *Right:* The $57,000,000 constituting the one per cent of our national budget allotted to this worthy cause of promoting the public knowledge is distributed among the various fields as here indicated.

**A graphic demonstration of how the Federal Government spends its money in the course of a year**

## Where Uncle Sam's Income Goes

By G. H. Dacy

OUR national budget for the recent fiscal year which ended July 1, aggregated $5,686,005,706. Of this vast appropriation only about one per cent, or $57,093,661 was devoted to research, educational and developmental activities. This money was used by the national Department of Agriculture, Geological Survey, Bureau of Mine, Coast and Geodetic Survey, Bureau of Standards, Bureau of Fisheries, Bureau of Foreign and Domestic Commerce, Bureau of Labor Statistics, Women and Children's Bureau, Vocational Education, State Colleges of Agriculture and Mechanical Arts, Library of Congress, Smithsonian Institution and the Public Health Service.

On the basis of a population of 110,000,000 people this total budget means the expenditure of $50 per capita as compared with an expenditure of only fifty cents a year per capita for research, investigational and educational activities. Of the total government appropriation for this year, 67.8 per cent was devoted to paying off a portion of the indebtedness which has obtained from recent and previous wars. This included interest on the public debt, railroad deficit, the maintenance of the Shipping Board, European food relief, soldiers' homes, bonuses, insurance and care of soldiers and pensions. It took 25 per cent of the gross funds to maintain the military enterprises of Uncle Sam; 3.2 per cent of the appropriation was devoted to the maintenance and operation of primary government functions such as Congress, the Executive, the Federal courts and similar national projects while another 3 per cent was used in supporting public works, including rivers and harbors, public buildings, reclamation service, post roads, national parks and the railway in Alaska.

The outstanding feature about the annual congressional appropriations is that only one per cent is devoted to promote scientific research, to increase production and to intensify efficiency, to develop wealth, to promote public health and to conserve our national resources. To the layman who carefully studies these figures it appears that Congress practices parsimony and economy backside forward when it minimizes the scientific and developmental funds. It is largely through these agencies that the wealth and financial resources of the country at large are increased. To impede their maximum development and operation is to curtail the potential productivity of many of the industries and allied activities.

The appropriation budget for the next fiscal year is drastically curtailed as concerns the funds made available for research and investigational enterprises. Instead of cutting the appropriations for the government enterprises which ordinarily exhaust at least 99 per cent of the total funds, Congress carved away at the moneys destined for scientific research to the extent that it will be necessary to abandon much important investigational work. For example, the national Department of Agriculture will have to give up more than 65 lines of experimentation which previously it has been engaged in. Much of this work is of a character which demands consecutive continuation year after year for permanently worth-while results.

About 62 per cent of the government funds appropriated for research and investigational operations are devoted to the work of the national Department of Agriculture. Agriculture is the most important industry of the nation and farming and animal products raised in the United States are worth at least $25,000,000,000 a year. It is of fundamental importance to city residents that agricultural production be maintained and increased with the relative growth of population. The Agricultural Department works with such ends in view: to increase production, to keep food prices within the reach of the masses, to promote the interest of the farmer in his work and to improve rural living conditions and make life in the country more pleasant and attractive. It is spending about $1.50 for every $1,000 of value of agricultural and animal products and, without question, the results achieved pay many times the cost of the work.

The investigational activities of the other government departments engaged in scientific research are almost as valuable to the country at large although not so extensive as those of the Federal farming scientists. Excluding food products, tobacco and liquors, the annual value of manufactured products in this country, over and above the value of the raw materials entering into them is approximately $12,000,000,000. Last year the funds available for the investigations of the Bureau of Standards only admitted of the national scientists spending $.15 per $1,000 of manufactured products in all its work and only one-half of this sum was devoted to work which promoted the development of such manufacturing enterprises.

The other national agencies referred to above have operated under similar handicap, due to similar financial shortages. Unless scientific research is to decline appreciably in this country, our future Congresses must be imbued with some far more rational sentiments than heretofore, so that they will loosen the Federal purse strings and apportion more money for experimental and investigational activities of this description.

## The Progress of the Einstein Judges

THE Einstein contest has now reached the stage where the participants are writing and telephoning to ask us when we are ever going to announce the winner. This, we suppose, was to be expected; certainly a bit of impatience may be pardoned in one who awaits an announcement involving himself and five thousand dollars. But we shall have to ask the contestants to display the same charity toward us that we are prepared to display toward them.

By a curious trick of fate, there were submitted in competition for the prize exactly 300 essays. Of course a few of these did not require serious consideration—this is inevitable in a contest of such magnitude. But after excluding all the essays that were admittedly not about the Einstein theories at all, and all those whose English was so execrable as to make them quite out of the question, and all those which took the subject so lightly as not to write reasonably close to the limit of 3,000 words, and all those which were [illegible] to explanation of the manner in which Einstein theories verify those of the writer, and all those in which the writer attempts to substitute his own cosmic scheme for Einstein's—after all this, there remained some 275 essays which were serious efforts to explain in simple terms the nature and content and consequences of Special and General Relativity.

Now there may be those who consider that two learned exponents of Einstein's doctrines ought to be able to rush through these 275 esays, allowing some ten minutes to each, and stating definitely at the conclusion of the process that No. 144 is unqualifiedly the best. Unfortunately, in practice it is not possible to do anything of the sort. It is necessary to read all the essays carefully, and not merely once but several times, gradually eliminating those which are not the best. As the number of survivors decreases it is necessary to bring to each essay a closer and ever closer scrutiny. Extreme care has to be taken in deciding whether the various essays preserve the proper balance between scientific accuracy and intelligibility of treatment. The final decision must perforce be a very delicate one: of several surviving essays that discuss the subject adequately and involve no material scientific infelicity, which embodies the best selection of material presented in the way best calculated to be understood by the intelligent general reader?

It is not the least of the difficulties involved that all this work has to be undertaken by the Einstein editor and the judges without disturbing any more than necessary the editorial routine, and without prejudicing at all the ordinary academic duties. It is therefore utterly out of the question to hang up any speed records in determining the winning essay. Early in the month, when we last communicated with the judges, the 275 had been reduced to 17, with a strong probability that of these, some half dozen would immediately fall by the wayside. But the long, hard pull will come in the effort to decide which of the last six or eight or ten is really the best combination of skilful planning and successful execution. We believe that the judges, with or without the final arbitration of the Einstein editor, will reach a decision in time for the winning essay to appear in one of our January issues. But it is entirely conceivable that the processes of final elimination may strike a snag that will make this out of the question. In any event, the contestants may be assured that their suspense will be ended, and the public at large that the prize essay will be presented in our pages, at the very earliest date possible.

Later we shall have something to say in detail about the character of the essays received, the scope of the contest, and other points of interest. For the present we may remark, as we have done explicitly on a previous occasion and implicitly just above, that the caliber of the essays submitted was on the whole high. There were many which would have been well worthy of the prize in the absence of others that were distinctly better—many which it was not possible to eliminate on the ground of specific faults, and which could only be adjudged "not the best" by detailed comparison with specific other essays. While nearly one-half of the essays followed substantially the same general outline, the other half showed almost as many ways of attacking the subject as if comprised of separate essays; so the aim of securing a wide diversity of treatment was fully realized. There is no slightest doubt that the contest has been a success; after the award of the prize our only embarrassment will be one of riches.

## Are We to Become the War Pace-Maker?

A FEW years ago, in the course of a political speech-making tour, the President made a complete right-about face from his previous attitude of deprecating any military preparation, by stating that the United States ought to have "incomparably the strongest navy in the world." The phrase was at once caught up by the Hearst papers and became the watch-word of certain politicians among us, who apparently would like to see the United States take the place of Germany as the armament pace-maker of the world.

The SCIENTIFIC AMERICAN always has, and always will, set its face firmly against such a movement; for we consider it to be not only opposed to the spirit and purpose of the United States, but absolutely unwarranted by the present naval and political condition throughout the world.

Before the World War, all Americans, the General Board of the Navy included, who believed in a vigorous naval policy considered that the naval defense of the country would be complete if the United States possessed the second strongest navy in the world. Thanks to our great building activity during the war, and to the fact that Germany, formerly the second power in strength, has been eliminated, the United States is not only the second naval power at the present time, but is so firmly established in that position that in dreadnaught and battleship strength, it is fully equal to the navies of Japan, France and Italy combined. Not only has the goal been reached, but we are established in the coveted position with a preponderance of strength never dreamed of at the time when the President and his naval secretary were strenuously opposed to making the increase in our armaments which would give us second place in naval rank.

The war has left behind it a legacy of heavy taxation and the people of this country are looking to Congress to set in force a too-long-delayed policy of drastic economy. Of the total Government budget, some seven-tenths or more is devoted to wars past and future and the small remnant to civil purposes. There is a very proper demand that the pruning knife shall be put in where it will produce the quickest results. It was the universal hope that expenditures, particularly in the Navy, would be brought down to a reasonable limit. Hence, the announcement that the Secretary is asking Congress for between 600 and 700 million dollars appropriation for the Navy this year has been received with something like consternation. The naval budget before the war ran somewhere in the neighborhood of 150 million dollars. Allowing for the higher cost of materials and for a larger personnel, et cetera, a budget of four hundred million dollars should have been sufficient. The call for nearly 700 million dollars would seem to indicate that the Navy Department has taken no note of the altered world conditions, or of the plea for a general easing of the burden of taxation.

It would be easily possible to reduce the appropriation without any prejudice to our naval interests. Thus, we have under construction eighteen capital ships at a time when all other nations except Japan have ceased such construction; moreover the work being done by Japan is limited as to amount. Construction of the six 43,000-ton battleships, costing $40,000,000 each, could very well be allowed to rest until the financial condition of the country and the exigencies of the naval situation render work upon them possible and advisable. This subject, however, we shall return to in more detail in a future issue.

We note in a dispatch to the press from Washington that there was brought to the attention of Secretary Daniels the suggestion of Senator Borah for an agreement between the United States, Great Britain and Japan to curtail naval construction for a period of five years. Commenting upon this, the Secretary is reported to have made the extraordinary statement that an alliance of this kind would be interpreted as an attempt by these three nations to dominate the world. We remember the day when the Secretary assured us that if the United States increased its armaments, it would have the same effect. In his mind at least, our beloved country is a disturbing influence in the world, whether we build ships and guns, or whether we agree not to build them. Mr. Daniels tells us that the world is still "shell-shocked." If so, he has certainly got his share of the trouble; for if we credit him with being sufficiently humanitarian to wish to get the world out of its shell-shocked condition, we find that apparently his method would be to put our Navy in the position to get the world more shell-shocked, by doubling our present strength in ships of war.

Furthermore the General Board of the Navy recommends that in these piping times of peace, when practically the whole of the world has quit warship building, we not only complete the eighteen capital ships and other ships that we are building, but that Congress authorize four more capital ships, 30 10,000-ton cruisers, 8 gunboats, 18 destroyer leaders, 12 long-radius mine-laying submarines, 6 cruising submarines, 4 airplane carriers, 3 destroyers and 3 submarine tenders, or some 90 ships in all.

And so the merry game goes on; while the Secretary of the Treasury plays his accompaniment, by suggesting that the income tax for the majority of us good people be raised from four to six per cent.

## The Promise of the Commercial Airship

WHEN "R-34" was in this country, in the summer of 1919, the officers in charge of the ship were unanimous in the belief that the commercial future of the airship was assured. This conviction was based upon the performance of "R-34" in crossing the Atlantic, and the certainty of an increase in the size of the airship, with all the well-known advantages which come with size, and secondly, upon certain experimental work which was then commencing, designed greatly to increase the carrying capacity and range of the airship by a more economical use of fuel.

Since that day, the Research Department of the Air Ministry has taken the matter in hand, and we understand that the preliminary investigations are full of promise. Stated in a general way, the economies which are aimed at are to be secured in two directions. The hydrogen which ordinarily is discharged is recovered and used in an engine designed for this purpose, and it is estimated that the value of the gasoline which will thus be saved will be sufficient to recover the cost of the hydrogen which is thus turned to useful account.

The reduction in the gross weight of an airship due to the consumption of gasoline, necessitates the discharge of hydrogen to compensate for the reduced weight. This hydrogen represents a dead loss. Experimental work is now being done in developing apparatus for condensing the water of combustion which passes out through the engine exhaust. It was this development to which the officers of "R-34" made particular reference in 1919, and the Research Department of the Air Ministry has found that it is possible to recover in this way a weight of water almost equal to the weight of fuel consumed; thus again reducing the amount of hydrogen which has to be discharged. Not only will there be a saving of hydrogen by these two methods, but in any given airship, it will be possible to carry a greater weight of passengers, mail, freight, et cetera.

## Aeronautics

**Sweden's Subsidy Plan.**—From a message from Stockholm it appears that the Swedish Government is determined to encourage the development of an aerial postal service. It has decided to subsidize the Swedish Air Traffic Company by the payment of 500 kroner for each journey between Malmoe, Copenhagen, and Warnemunde. This scheme of subsidizing aerial travel companies has already been put into effect in other countries, with satisfactory results.

**The Helicopter Problem.**—Slowly but surely it appears that the helicopter problem is being solved. For one thing it is no longer being handled in a haphazard, hit-or-miss, guess-work manner. It is now receiving the attention of engineers and scientists who do not go into anything without acquainting themselves first of all with the mathematics and mechanics and the whys and wherefores. From *Aeronautics* we learn that M. Damblanc of France has recently carried out some experiments with a full-sized direct-lift machine under the auspices of the French Government. He is believed to be the leading authority on this subject at the moment. The development of a practical machine of this nature is of great importance, particularly to commercial aviators.

**America's Speed Record.**—The winner of the Pulitzer Trophy race held last Thanksgiving Day at Mitchel Field, Long Island, was Lieut. C. C. Mosley of the United States Army Air Service, who piloted the Verville-Packard American-built airplane to victory. The engine of this machine is the Packard 600-horse-power engine, designed by Col. Jesse G. Vincent. The Verville-Packard machine attained a speed of 178 miles per hour, thus marking a new record for American planes and engines. The Verville-Packard airplane is at present being overhauled at McCook Field and certain changes are being made in the gasoline feed, in the belief that when these are completed it will be possible to reach a speed well beyond 200 miles an hour and thus break all records.

**A Small-Airplane Contest.**—In view of the political situation in Italy preventing the entrants from having their machines ready in time, it has been decided to postpone the international competition for the Mapelli Cup. At this writing the contest has perhaps taken place, although we await such news with interest, together with the details. This cup has been offered by Mr. Luigi Mapelli for an annual competition for aircraft "having a wing-spread of not more than 6 meters over all, and driven by engines of total stroke-volume up to 4,585 cu. mil. inclusive." The competition is a speed one, and each succeeding race is to be for twice the distance of the preceding one. For this year the course selected is over a distance of 182 kilometers. At each of the designated points on the course the competitors will have to come down for three minutes, and the machine which completes the course in the shortest time will win the cup.

**A German Gliding and Soaring Competition** was recently held in the Rhön district by the League of German Model Aircraft and Gliding Clubs. The meeting was marred by one unfortunate accident, resulting in the death of the well-known pilot, von Loessl. This was due to breaking in the air of the elevator of his glider. A number of monoplanes and biplanes were entered, some of very novel design. Many of the entries had comfortable seats and landing gear, as distinguished from the old-time gliders in which the operator's legs swung below the planes, ready to take up the strain of a hard landing, often at the price of serious injuries. The longest distance covered by the gliders was 1,830 meters, with a duration of 142.5 seconds. That record was made by Klemperer, with a height of 330 meters. The apparent gliding angle of Klemperer's flight was one in thirty-one.

**Airplane and Seaplane Design Prizes.**—The British Air Ministry offered prizes totaling £64,000 for the best designs of airplanes and seaplanes; half of this sum was for large airplanes, £16,000 for small airplanes, and £16,000 for seaplanes. In the airplane competition only £24,000, or one half of the total, has been awarded, because the results "show less radical advance in general design than had been anticipated." In the seaplane class it is stated that a great advance in design and efficiency has been shown, and because of the excellence of the machines the second prize has been increased to £8,000 from the original £4,000, which was offered. Each machine had to have accommodations for four passengers, and the tests included rising from and alighting on both water and land, as well as making a figure-of-eight course on the water around two buoys placed within a rectangle measuring 200 by 100 yards. It is understood that a full technical report on all classes of the machine will be issued.

## Science

**A Reservation for the Australian Aborigines.**—The commonwealth of Australia has taken steps for the preservation of the aborigines of that country, and has assigned a tract of public lands in the Northern Territories as reservation for the tribes. It includes the Mann and Petersen Ranges and practically the whole of Lake Amadeus. The governments of South and Western Australia have set aside adjoining areas for the purpose of this reservation.

**Public Health Engineering Abstracts.**—A new feature of the *Public Health Reports*, issued wekely by the U. S. Public Health Service, is the occasional publication of a batch of abstracts of current literature relating to sanitary engineering. The following list of titles from a recent instalment of abstracts gives an idea of the scope of the undertaking. All abstracts are short. "Protection of Surface Water Supplies Against Contamination," "Activities of the Division of Engineering of the Illinois Department of Public Health," "Nitrate Content of Certain Waters Considered Bacteriologically Safe," "Design of Aspirators for Sterilizing Waters," "The Water Supply of the American Expeditionary Forces," "Report of Sewage Experimental Investigations at West New Brighton, N. Y."

**The Crop Protection Institute.**—Under this name, and with the advice and assistance of the National Research Council, has been organized an association for studying insect pests and plant diseases and improving methods of fighting these scourges of agriculture. The temporary secretary of the Institute is Mr. Harrison E. Howe, chairman of the Division of Research Extension of the National Research Council, while the board of trustees includes nine scientific men representing leading organizations interested in crop protection and four representatives of industrial concerns manufacturing chemicals and appliances used in combating crop pests and diseases. There is always room for research in plant pathology. It is estimated that, in a recent year, the black-stem rust alone was responsible for the loss of 180,000,000 bushels of wheat in this country.

**A New Cryogenic Laboratory.**—One of the most interesting pieces of scientific news that has recently come from Washington is the announcement by Dr. R. B. Moore, of the Bureau of Mines, that his Bureau is installing a first-rate laboratory for low-temperature research. The immediate purpose of establishing the laboratory is to obtain data needed by the Government helium plants, but, says Dr. Moore, "there is a strong desire that this laboratory shall be of material use to science in general, and that it may be possible later on to make arrangements for its facilities to be used in special cases by men outside the Government service who are specially equipped for such work." The equipment includes two four-stage Norwalk compressors with a capacity of 75 cubic feet of free air per minute, which will be used for making liquid air and other purposes. There is also a vertical submarine type Norwalk compressor with a capacity of 12 cubic feet of air per minute to be used in connection with a liquid hydrogen cycle, and a similar compressor of smaller capacity for use in connection with a liquid helium cycle. The staff will include four technical men and two mechanics, under the direction of Dr. Moore.

**The Campaign Against Rats.**—A special conference of state health officers with the U. S. Public Health Service was held in Texas last August to consider the bubonic plague situation, and the resolution was adopted that "a nation-wide effort should be made to determine as accurately as possible the presence or absence of rodent plague in all ports of entry and principal centers of railway freight transportation in the United States," and further that the present situation in the southern states "should be the occasion for inaugurating a nation-wide campaign against rodents on economic as well as public health grounds." In this connection the Public Health Service has published full instructions concerning rat surveys and rat proofing and has drawn up a model building ordinance with a view to eliminating rats. It is a fact not generally recognized that, apart from their well-known powers of spreading disease, rats impose a very serious economic burden upon the community. In this country it is estimated that their depredations amount to $167,000,000 a year. The rat population of the United States is conservatively estimated to be equal to the human population, and similar figures have been published for Great Britain, Denmark, France and Germany. The annual upkeep per rodent is estimated at $1.80 in Great Britain, $1.20 in Denmark, and $1.00 in France. (These are pre-war figures.)

## Industrial Efficiency

**Pulverized Lignite** or brown coal is being used as fuel in Australia. The lignite is mined in either shafts or open cuts, the coal crushed on the spot to egg size, then hoisted to the air-drying tipples at the surface by bucket conveyors. After drying about seven days, the coal is relieved of practically half of its moisture content and is ready for final treatment. This final process, which should be undertaken near the place where the fuel is to be used, consists of again crushing the coal—to about ½-inch mesh—after which it is passed through a rotary drier, where the moisture content is reduced to about 10 per cent. The fuel is then pulverized, separated by air, and stored in bunkers.

**Germany's Modified Barter System.**—One development of the impasse in import and export business between Germany and other countries growing out of the depressed value of the German mark has come as a modification of the barter system. Arrangements have been made by various British interests whereby there is practically an agreement on the part of German manufacturers to manufacture goods for account of the British or other interests out of raw materials furnished by the latter and for a percentage of the goods as a commission or profit. Most of the work in this line has been done by British cotton interests who have arranged to furnish German cotton mills with raw cotton and take from them cotton yarn manufactured therefrom, the German manufacturers retaining a portion of the yarn as their payment for the use of their plant, of their labor and fuel outlays, and other costs of manufacture.

**An Inserted-Tooth Metal Saw** which promises to meet a long felt demand has been invented, and is being placed on the market. This saw was especially designed to meet the requirements for a saw to cut structural iron, I-beams, channels and stock with thin walls that could not be cut so successfully with other saws of similar design, because the pitch or spacing of the teeth was not fine enough to keep two teeth in the cut at all times in this work. This new saw through its arrangement and closer spacing of teeth provides for smoother running and eliminates chatter which is often noted where the teeth are placed farther apart in the plate. It is a fast cutting saw and is fitted with as many teeth as it is possible to fasten securely into the plate while retaining the perfect alinement of teeth and strength of plate necessary to stand up and cut true. These saws are being made from 10 inches in diameter with kerf of ¼ inch and maximum of 40 teeth, to 50 inches in diameter, 15/32 inch or 7/16 inch kerf with 210 teeth as the maximum number.

**Europe's Interest in American Advertising** is steadily growing. Certain American periodicals have lately been asked by European manufacturers about rates, circulation, and other data of interest to prospective advertisers. Most of these inquiries are from Holland and Germany, although not a few are from France and Great Britain, with a lesser number from Italy. European manufacturers are beginning to face a serious over-production so far as their home market is concerned, and it is altogether to be expected that they are casting covetous eyes toward the Amerian market. They evidently intend advertising their wares in the very near future. Because of the rate of exchange, they can undersell American products in many different fields while still making a handsome profit for themselves—at least under the existing tariff. We have already seen the new European efforts in cameras and lenses, certain chemicals and drugs, print paper, toys, books, fine instruments, photographic supplies, and so on. Are these but the vanguard of a formidable European invasion?

**Industrial Machinery in France and Belgium.**—"Europeans have overestimated their capacity for rehabilitating their industries. . . . American cooperation applied to the reconstitution of essential producing industries would provide a considerable market for American industrial machinery and at the same time would insure raw materials and more work for European machinery factories. . . . More needs to be done to gain the confidence of European industrialists." The foregoing are the expressed opinions of Trade Commissioner Charles P. Wood in a report on industrial machinery in France and Belgium just published by the Bureau of Foreign and Domestic Commerce of the Department of Commerce. The publication is known as Special Agents Series No. 204, "Industrial Machinery in France and Belgium." Copies can be purchased for 10 cents from the Superintendent of Documents, Government Printing Office, Washington, D. C., and from the district and coöperative offices of the Bureau of Foreign and Domestic Commerce located in different cities.

# Our Lagging Gold Production

## Reasons Why Less of the Precious Metal Is Being Produced Now Than for Many Years Past

By Arthur L. Dahl

WILL the world run short of gold? This is a question that is bothering our economists, and the answer is not as reassuring as it might be. Individuals have grown accustomed to the absence of the golden eagle from their pockets, but they had the vague comfort of believing that there was a big pot of gold somewhere in the world, and that being a basic metal it would be impossible to lose any permanently. But an analysis of the world's statistics shows that gold production is not keeping pace with the demands, and that unless its use for the arts and sciences is restricted, there will not be enough to support the tremendous expansion of credit which is based upon the gold standard.

In the last 425 years of which we have records of gold production, the total amount of the precious metal taken from the earth and added to the world's supply was only a little more than seventeen billion dollars. Of this production over half was mined in the last 25 years, during which period the average annual production of new gold is approximately $375,000,000. Of this the United States produces less than $100,000,000, and this production is gradually diminishing from various causes.

The quantity of gold used in the arts has increased by leaps and bounds until now it amounts to about $40,000,000 annually in the United States alone. It is estimated that there is about $9,000,000,000 in gold in the national and bank reserves of the world, and of this amount the United States holds over one-third, or an increase of more than two billion dollars since 1900.

In spite of the fact that gold is distributed in every continent and is mined in about 60 different countries, its production has never been considerable in any one locality, with a few possible exceptions. The gold fields of the Transvaal, South Africa, are the heaviest producers, and now yield about 40 per cent of the world's gold, as against about 20 per cent from the United States. The Transvaal mines employ 200,000 natives and 20,000 white men, or more than are employed in all the metalliferous mines in the United States. In the United States, gold production, although constantly diminishing, has been kept up to present figures largely through the operation of gold dredges, which extract the grains of gold from lands incapable of being profitably mined by other methods.

The gold output of the world seems to have passed its zenith and to be on the decline. Existing ore bodies are being worked out and few new ore bodies of importance have been added to the gold and silver producers in recent years. Much of the gold now produced is taken from low-grade ores that are profitably worked only because of the improved technique in mining and metallurgy developed by engineers. The yields and costs vary in different districts and in different mines in each district. The greatest gold producers have been mines of low or moderate yield per ton, but with great mass occurrence and good conditions for economical working. For example, the Homestake mine in South Dakota, which has been working since 1875 and has produced over $147,000,000, has operated entirely in low-grade ore averaging not over $4 per ton, and yet this mine has made a profit of over $40,000,000, or 27 per cent of its output. Another famous mine, that of the Alaska Treadwell group in Alaska, has crushed and treated 26,000,000 tons of ore, yielding $63,000,000, or $2.37 per ton, and at a cost of $1.42 per ton. Another Alaska mine is reported to have worked over 2,000,000 tons of ore giving a yield of less than $1 per ton, and yet made a profit, but this is only possible by a combination of unusually favorable natural conditions and a most efficient organization backed by ample capital.

Since the beginning of gold mining in the Witwatersrand district, South Africa, in 1887, there has been produced there a total of $2,571,992,355 with a gross profit of over $600,000,000, but while production is holding up pretty well in this district there is no present likelihood of developing new and unknown deposits, and a steady decline is looked for in the African fields.

Australia reached the maximum of its production in 1903, when $87,000,000 in gold was mined, but since then it has gradually declined, until in 1916 the returns were only about $39,000,000. Canada, too, has declined from a production of $28,000,000 in 1900 to less than $15,000,000 in 1917. Russia and Siberia in 1914 mined about $28,000,000 of gold, but in 1918 this figure had dropped to $12,000,000. The same story is told of all other gold-producing countries, including the United States, for in 1919 the world produced but $350,000,000 in gold—$31,000,000 or 8.1 per cent less than for the preceding year. With this loss for 1919, the total amount of the decline in the world's gold production for the past four years was $119,000,000 or over 25 per cent.

The United States has been, probably, the largest gold-producing country on earth, for up to 1917 it had mined a total of $3,912,,708,000. In 1915 it produced over $101,000,000, but in the following years it has gradually declined in production until in 1918 the gold amounted to only $68,646,700. There are six States and the territory of Alaska that have for the last six years produced approximately 90 per cent of the gold of this country. They are, in the order of their production, California, Colorado, Alaska, Nevada, South Dakota, Arizona and Montana. For the last two years all of these States have shown marked declines in the amount of gold produced, and the lode or quartz mines have shown the greatest falling off, largely due to the increased cost of mining, compared with the fixed value of the gold recovered. California and Alaska have maintained their output largely through the operation of gold dredges, which, though feeling the effects of the increased cost of production, had to keep operating on account of the maintenance of their organizations and the indirect loss that would be sustained by

## The North Platte Project Today

**By J. F. Springer**

A PORTION of the Fort Laramie Unit of the North Platte irrigation enterprise was thrown open on March 5, 1920, to men who had been in the Government's military service in the Great War. There were only 79 farms offered for entry, and yet 9,000 men sought information as to the offer and about 1,500 ex-soldiers actually assembled at Torrington, Wyoming, to compete for the land. Some 10,000 acres were actually allotted. These facts illustrate two things: (1) That the experience of earlier settlers on reclaimed territory at other points has been good, and (2) that ex-soldiers are rather eager for farm homes.

The North Platte project, viewed as a whole, is one of the greatest anywhere. It is already guaranteeing 14,000 farms against drouth by means of its 12,000 main canals and ditches. The crops thus provided for are worth annually some $80,000,000. The value of these irrigated lands runs up to $200,000,000. These statements represent what has been accomplished. The recent competition at Torrington illustrates the fact that the enterprise is still being developed. This great project contemplates, in fact, the absolute control of a great river and the utilization of its waters to just about the limit of the possibilities.

The controlling feature in the project is Pathfinder Dam. This structure cost upward of $1,200,000 and has been and is one of the notable dams of the world. It is 218 feet high, and has a length along the crest of 600 feet. It stands in a canyon where the great river passes between granite cliffs that are almost vertical, they are so steep. The dam was constructed largely of the granite found on the spot. Nevertheless, from the distant railway (C. B. & Q. R. R.), the construction machinery, the general supplies, the necessary cement, and so on, had to be painfully transported across the intervening desert. The power plant was located high up on the cliffs above the site of the dam. Cableways strung across the canyon assisted in handling the work. Excavating to a depth of 12 feet, the workmen came upon bedrock. Big cranes or derricks were stationed down at the bottom of the canyon and along the sides. And a great tunnel was cut for the purpose of passing the waters of the stream during construction. However, real floods had to be dealt with, and these simply swept over the work, leaving it intact.

Dynamite, pluck and engineering knowledge and equipment proved themselves competent to attack and solve this problem, and to do it economically as well. The lake created by damming the North Platte at this point has a storage capacity of 1,025,000 acre-feet—enough water to flood the whole State of Rhode Island to the depth of a foot. It is said, in effect, that the capacity is only a trifle less than the combined storage capacities of the Wachusett, New Croton and Ashokan reservoirs. The masonry of the dam amounts to 60,400 cubic yards. Despite the fact that the site of this dam is located 45 miles from the nearest railroad, the cost of construction was very moderate. The entire river is controlled. This was a big conception. The Platte is a very long stream rising in the mountains of Colorado and flowing through a large part of Wyoming and dividing the whole State of Nebraska lengthwise. The head-waters lie between the Medicine Bow and the Sierra Madre ranges, near the Continental Divide in north Colorado. On the other side of this Divide, but farther north and west, are the head waters of one fork of the Snake River. The one sends its waters to the Gulf of Mexico and the Atlantic Ocean, while the other contributes to the Pacific Ocean. The North Platte and Snake figure in great irrigation enterprises.

**Lower face of the Pathfinder dam, showing the discharge of 6,500 second-feet**

Pathfinder Dam is located far up in the valley of the North Platte at a point some three miles below the location where the Sweetwater River joins the main stream. This is in central Wyoming in a very elevated region. This may be understood from the fact that

**Measuring the hardness of rock by means of its resistance to grinding**

## How Hard Is a Rock?

**By S. R. Winters**

THIS is a question which appears to be quite as empty and meaningless as another inquiry, "How sour is vinegar?" Rocks, however, vary in quality as well as other substances of less pronounced characteristics and in road building it is essential that only the choicest specimens be selected. To the farmer who is ridding his estate of stony obstructions, rocks have no pereferential rating, the entire unassorted formation being objectionable. Builders of highways classify them with respect to their relative hardness, toughness and binding power.

Clearly, physical properties of rocks are not to be determined at a cursory glance, the material entering into the construction of macadam roads undergoing exacting laboratory requirements as a guarantee of its resistance to the wearing action of traffic, especially iron-tired vehicles. A machine in use in the laboratory of the United States Bureau of Public Roads literally separates the brittle rocks from the hard ones, setting its seal of approval upon the latter. Hardness, as it applies to rocks used in constructing roads, is that quality which successfully resists the tendency of vehicles to convert into dust fragments of rock forming the wearing course of a macadam road. Toughness implies ability to resist fracture under the pounding pressure of traffic, while binding power indicates the capacity which dust of a rock possesses or develops by contact with water for welding or cementing the larger rock fragments together. Such a quality is the tie that binds when the shearing action of traffic is spending its force, a condition especially desirable in water-bound macadam construction, where it is relied upon to maintain the integrity of the wearing course as the road surface is shaved away by vehicular traffic.

The machine, shown in the accompanying photograph, reflects the relative hardness of rocks. It consists of a circular steel disk, which is revolved in a horizontal plane by bevel gear driven by a pulley. A brass grip clutches the test specimen, the clasp being held in a vertical position over the steel disk by inserting it in the sleeve. The latter is of such dimensions as to constitute a sliding fit, permitting free vertical movement but forestalls a sidewise tendency of the grip. Crushed quartz, the laboratory wearing material, is fed on to the disk through a funnel, the lower end of which forms an opening one-fourth of an inch in diameter. The sleeve is so situated that the center of the grip, when in position, will be 26 centimeters from the center of the rotation of the disk. A galvanized-iron hopper, located under the disk, receives and conveys away the used sand.

Crushed quartz, as the abrasive agent, is screened for passage through a standard sieve with 30 meshes to the linear inch and is retained on a standard sieve having 40 meshes per linear inch. Commercial sand of this specification is not easily available, so it is a practice to specify a sand not more than 5 per cent of which will be retained on a No. 30 sieve and not more than 25 per cent of which will pass a No. 40 sieve. A core 25 millimeters in diameter and 10 centimeters long is cut with a diamond drill from the specimen subjected to the hardness test. Once thoroughly dried, the piece of rock is placed in the brass grip of the testing machine, leaving one inch projecting from the lower end. The grip is inserted in the sleeve, the lower end of the specimen resting on the steel disk. The funnel is filled with sand and the machine operated until the lower end of the rock has worn away, down to the plane of the disk.

# Why the Cliff Dwellers Vanished

## A Modern Industrial Hazard that May Have Existed in Prehistoric Times

By Frederick L. Hoffman

THERE can hardly be a more interesting speculation than the racial origin and the rise and fall of what must once have been a considerable population of a region now marked only by the ruins, the shrines and the temples brought to light by patient excavation throughout vast areas of the great Southwest. It hardly admits of a dispute that the original cliff-dwellers, as they are most familiarly known, had passed away long before the Spaniards visited that region and, beginning with about 1759, inscribed their names on Inscription Rock, now fortunately a national monument. That the aboriginal life was extensive in area and that the population was considerable in numbers is made evident by the many ruins, nowhere so clearly indicated as in Mesa Verde Park in southeastern Colorado, just north of the New Mexico line. On the topographic survey map of Mesa Verde Park five hundred and seven ruins are indicated, differentiating cliff-dwellings and remnants of the Pueblo type. Two hundred and two of these ruins are located within a distance of five miles from Cliff Palace, and within a radius of ten miles from this central point may be found no less than ninety-five per cent of the entire colony of identified ruins. Of the five hundred and seven distinct ruins fifty-two and a half per cent are located on the left-hand side of the canyons, as opposed to forty-seven and a half per cent on the right-hand side. The entire area is two hundred and eighteen square miles in extent, including a portion of the Southern Ute Reservation and the great Montezuma Valley, which touches the southern border of Utah.

This area is not symmetrical in its relation to what was probably the center of religious life and industrial activity, readily identified by the ruins of Cliff Palace and Sun Temple, which lie just north of the State line. It is, therefore, difficult, if not impossible, to estimate even approximately the probable population of this area, since it is practically certain that further excavations will reveal numerous ruins in adjacent territory, as yet but superficially explored. It is most regrettable that practically all the accounts of archaeological explorations in the Southwest should be wanting in maps useful for the purpose of tracing known ruins with certainty, both as to location and type. There would seem to be no excuse why such an elaborate work as the report on the "Explorations in Northeastern Arizona" by Kiddle and Guernsey should be entirely wanting in a map, without which all estimates of the probable population must be a matter of mere guesswork opinion. As an admirable illustration of the type of maps useful for the purpose, although on a scale hardly sufficient for exact identification, reference may be made to the really extraordinary dissertation on ancient communities in the American Desert, published by Prof. Edgar L. Hewett, in French; Geneva, 1908. (*Les Communautes Anciences dans les Desert Americain*).

### Primitive Stone-Working Technique

The condition of these ruins, many of which have only been brought to light during very recent years, particularly under the direction of Prof. Jesse Walter Fewkes, of the Bureau of Ethnology, is indicative of a relatively high degree of attained civilization by a population thoroughly representative of the late Stone Age. An immense number of stone implements have been found, suggestive of the conclusion that the stone work of these ancient inhabitants was the predominating industry, universally carried on as a matter of paramount necessity by a considerable portion of the male population. The processes employed in shaping or manipulating stone materials by our early Indian tribes have been learnedly discussed by numerous writers, but for the present purpose it will be sufficient to quote from a contribution by Professor Holmes to the "Handbook of American Indians" the statement that there were used "(1) fracturing processes, variously known as breaking, spalling, chipping, flaking; (2) crumbling processes, as battering, pecking; (3) incising or cutting processes; (4) abrading processes, as sawing, drilling, scraping and grinding; (5) polishing processes."

We have in this description all the elements typical of an industry which in modern times has been materially modified only by the introduction of iron and steel tools on the one hand, and pneumatic cutting methods on the other. The labor in the primitive stone industry must not only have been much more arduous and exacting (for years must have been necessary to produce some article of special merit), but it is also safe to assume that the industry must have had a most important bearing upon the health, physical strength and disease liability of the cliff-dwellers.

That the ancient stone work was in many respects a craft, requiring a much higher degree of specialized individual skill than the modern mechanical processes, is made evident by a further observation by Professor Holmes, who remarks that, "In shaping blades a suitable piece of brittle stone, preferably a flattish pebble, bowler, flake or fragment was selected, and with a hammer-stone of proper weight, usually globular or discoidal in form and generally not hafted, chips were removed by means of vigorous blows about the periphery, alternating the faces. The utmost skill of the operator was exerted to cause the flakes to carry from the point of percussion near the edge across and beyond the middle of the sides of the stone, failure in this resulted in the formation of a high ridge or node on one or both faces of the blade, which effectually prevented the proper development of the form."

### The Atmosphere of the Stone Workers

The foregoing statement emphasizes the conclusion that in ancient stone work the processes, the personal exposure to health-injurious conditions and the after-effects may possibly have been even more serious than is the case at the present time. The effects of stone work vary, of course, according to the chemical and microscopical nature of the dust inhaled in considerable quantities during the working processes. While granite dust is probably the most injurious, limestone, bluestone, and slate dust are unquestionably less harmful. Thus far no scientific observations appear to have been made a matter of record, clearly disclosing the nature of the different rocks out of which the ancient cliff-dwellers carved their dwellings or by laborious manipulations made the tools indispensable to the needs of primitive life. In many sections the remaining work indicates the extraordinary amount of skill and painstaking care in the cutting and surfacing of stones used for walls or in the building of community dwellings, underground kiwas, etc. The best illustrations of ancient dwellings or cliff-alcoves (originally some back rooms of talus pueblos) are contained in Report No. 5 of the Archaeological Institute of America on the "Excavation of Tyuonyi, New Mexico" by Prof. Edgar L. Hewett. This paper was followed by an equally interesting report, including numerous illustrations of rock dwellings with floor plans and tables of dimensions and in Paper No. 10 on the "Excavation of El Rito de los Frijoles." Both of these papers were issued at Santa Fe, N. M., in 1909 by the Archaeological Institute of America.

It is not generally known that the disease resulting from the continuous and considerable inhalation of stone dust is not primarily pulmonary tuberculosis, but fibroid lung disease, which may or may not, according to the chance of exposure, result in a subsequent tubercular infection. In other words, even if pulmonary tuberculosis did not occur among the ancient cliff-dwellers, there cannot be the slightest doubt but that fibroid lung disease must have prevailed to an extraordinary extent among the stone-workers during the period when the stone industry had reached its highest development or near the date when the ancient civilization had practically come to an end.

*IN many parts of our Southwest it is clear that we have the remains of what once must have been a rather numerous and certainly a partially civilized race. But the cliff-dwellings are empty, and their builders vanished—so long vanished, in fact, that even among the pueblo dwellers who succeeded them little or nothing is known of them and their fate. It seems plain enough that these later people did not drive their predecessors out by force; had they done so, they would certainly have preserved this heroic event in their history through song and story. A rational answer to the question "What became of the cliff-dwellers?" is attempted in this article by Dr. Hoffman, and whether one agrees with his conclusions or not, it must be admitted that a really rational answer is what he gives.*—THE EDITOR.

### Dwellings Carved from Solid Rock

But there is another aspect to this question to which attention may properly be directed. Anyone who carefully examines into the rock dwellings, particularly as observed in Frijoles Canyon, must needs have been amazed at the enormous amount of labor involved in the literally carving out of the solid rock of the many large and small rooms, or cliff-dwellings, extant at the present time. These rooms are almost invariably dark and the dust exposure during the process of working, as well as later, during occupation, must have been considerable, if not enormous. After carefully examining into many such dwellings (for I have not had the dust either chemically or microscopically examined), there remains no doubt in my mind that the health-injurious consequences of the stone industry, both in its industrial and home-building aspects, must have been, in the long run, disastrous to health and life.

According to Professor Holmes: "Owing to differences in the composition of the rocky strata, the natural shelters occupied by the cliff-dwellers are greatly varied in character. While many are mere horizontal crevices or isolated niches, large enough only for men to crawl into and build small stone lodges, there are extensive chambers, with comparatively level floors, and with roofs opening outward in great sweeps of solid rock surface, more imposing than any structure built by human hands. These latter are capable of accommodating not merely single households, but communities of considerable size. The niches occur at all levels in cliffs rising to the height of nearly a thousand feet and are often approached with great difficulty from below, or, in rare cases, from above. Where the way is very steep, niche stairways were cut in the rock face, making approach possible."

I have given this extract also in its entirety, to convey as clearly as it is possible a picture of the ancient domestic life of these people, due to the practically unbelievable natural difficulties overcome in countless instances, which would seem to defy the power of human adaptation. But there must have been continuous exposure to stone dust in all essential operations, from road-building to home-building, and from the making of corn-grinders to spear-heads and battle-axes. As said by Professor Holmes: "The masonry is excellent and while the stones were rarely dressed, they were carefully selected, so that the wall surface was even and in some cases a decorative effect was given by alternating layers of smaller and larger pieces and by chinking crevasses with spalls.

"The walls were sometimes plastered inside and out with clay paint. The doorways were small and squarish, and often did not extend to the floor, except an opening or square notch in the center for the passage of the feet. The lintels were stone slabs, or consisted of a number of sticks or small timbers. Windows or outlook apertures were numerous and generally small."

### A Passion for Death-Dealing Labor

All of this would seem to indicate an almost unbelievable amount of manual labor on the part of a remnant of what must once have been an extensive civilization. Another essential fact, which requires to be kept in mind, is as pointed out by Professor Holmes, that "The cliff-dwellings to which the term 'cavate' is applied, are not built, but *dug* in the cliffs." The ruins of today are of course but the survival of vast pre-existing building operations, and, as said by Dr. Prudden "Excavations which have been made in several places show that buildings themselves of great age have been made on the top of still older structures." These digging and building processes must have involved a very considerable, if not disastrous, exposure to health-injurious dust. Even at the present time the dwellings contain dust accumulations, which would seem to indicate that the process of dust inhalation must have been practically continuous and universal. While modern stone-cutting is more injurious, on account of the use of pneumatic tools, there are at least the advantages of qualified medical aid, of more nourishing food, of better conditions of home life and prolonged periods of rest, with

(*Continued on page 641*)

## The New President of the American Association

**By Marcus Benjamin Ph.D.**

THE American Association for the Advancement of Science has had three wonderful permanent secretaries, each of whom has enrolled his name for all time among those of the great men on the roster of American Science. The able Lovering gave place to the genial Putnam, who in turn passed the mantle on to the brilliant Howard. Each of these three men was rewarded at the close of his term of office by an election to the highest place in the gift of the association.

Leland Ossian Howard is the son of Ossian Gregory and Lucy Dunham Howard, and was born in Rockford, Ill., on June 11, 1857. In early boyhood his parents settled in Ithaca, N. Y., where he was prepared for college and then naturally entered Cornell, in which university he pursued the modern course and graduated as B.S. in 1877. For a year he continued at Cornell, following post-graduate work preliminary to medical studies, including special courses in entomology—a subject to which he had been devoted as a child—under John H. Comstock, now the Nestor of American entomologists.

His ability in this branch of natural science was apparent from the beginning, and a vacancy in the entomological service in the U. S. Department of Agriculture becoming available led to his appointment as assistant entomologist to the Bureau of Entomology in 1878, with which service he has since continued, becoming chief in 1894. During these years he has also held the office of Honorary Curator of the Division of Insects in the U. S. National Museum, the duties of which are scarcely secondary to those of his office in the Department of Agriculture. Dr. Howard has also served as consulting entomologist to the U. S. Public Health Service since 1904 and at present he is also a member of the Executive Committee of the National Research Council.

During these many years rich with the fruits of patient research and the practical applications of their results, he himself notwithstanding the heavy duties of his administrative work, has made time to study parasitic insects and their utilization as enemies of crop pests. The introduction of the European and Japanese natural enemies of the gipsy moth and the brown-tailed moth was done at his suggestion and under his direction. Also, he deserves special credit for his work on medical entomology, such as the carriage of disease by insects. His writings on mosquitoes and the house fly have been of very great assistance to persons engaged in the fight against those disease-bearing insects, and the early measures against mosquitoes in Havana and Panama were based upon his published recommendations.

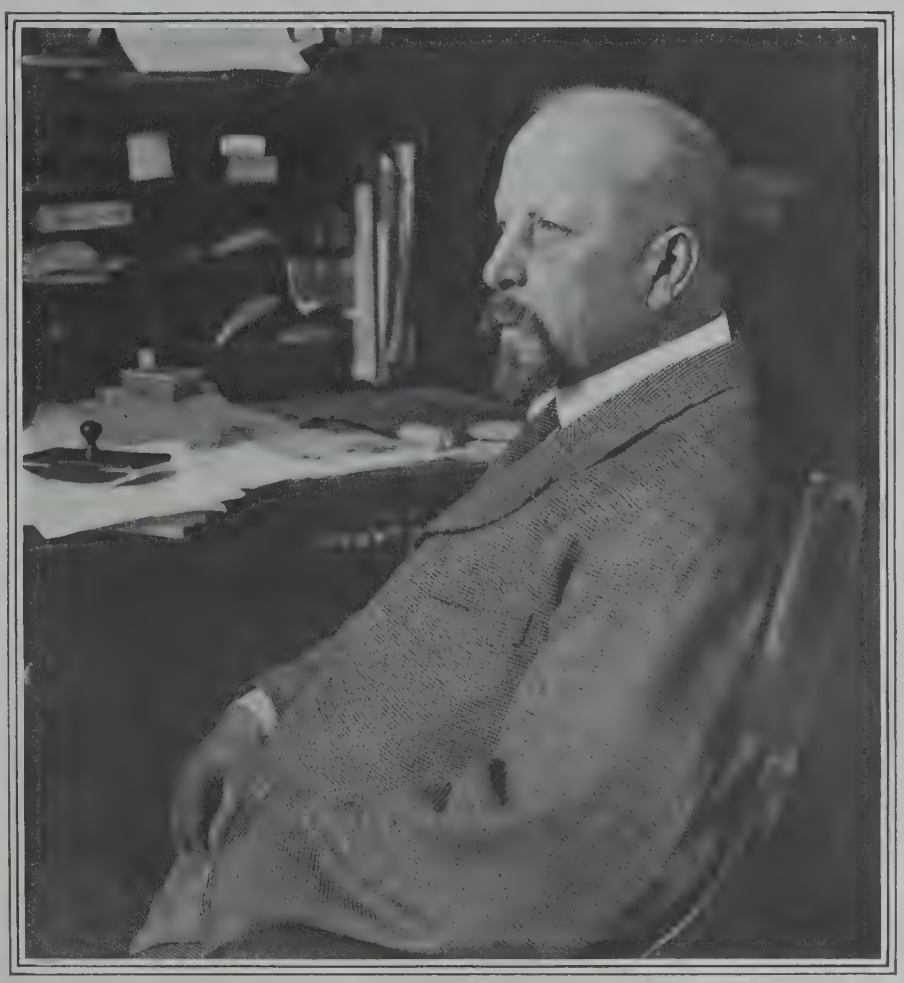
His remarkable industry and untiring energy is further manifested in a scientific bibliography that comprises over eight hundred separate titles, and he is the author in book form of "Mosquitoes—How They Live," etc. (1901); "The Insect Book," (1902); and "Mosquitoes of North America," (1912). Besides these he was for some years the editor of "Insect Life," a technical journal published by the Department of Agriculture, as well as preparing definitions in entomology for the Century and Standard dictionaries and writing articles on his specialty for the New International Encyclopedia and other works of reference.

His ability to present in popular language the technicalities of his specialty led to lectureships at Swarthmore College and at the post-graduate school of Georgetown University. He has lectured frequently before the Brooklyn Institute of Arts and Sciences and in 1901 gave a course before the Lowell Institute, in Boston, Mass. The first Sir Sanford Flemming Foundation lecture in Toronto was given by him, as well as the public lecture before the Royal Society of Canada in 1903.

His work has not failed to receive deserved recognition. The degree of M.S. came to him from Cornell in 1883, and that of Ph.D. from Georgetown in 1896, while in 1911 he received the honorary conferment of M.D. from George Washington and of LL.D. from Pittsburgh. Also, during 1900-5 he was an alumni trustee of Cornell.

Besides having held the presidency of the Association of Economic Entomologists (1894), the Biological Society of Washington (1897-8), the Cosmos Club (1909), the Washington Academy of Science (1916), the Entomological Society of America (1919), he is a member of the American Philosophical Society, the American Academy of Arts and Sciences and the National Academy of Sciences. In addition to corresponding membership in a number of European academies and learned societies, he is an honorary member of the Entomological Societies of London, France, and Stockholm, of the Royal League of Agriculture of Portugal, the Association of Economic Biologists of Great Britain, the National Society of Acclimatization of France, and one of the two American members of the Academy of Agriculture of France.

Dr. Howard became a member of the American Association at its Cleveland meeting in 1888 and a year later was advanced to the grade of Fellow. In 1893 he was chosen secretary of Section F in Zoölogy and served that section again in 1895 as its chairman and once more in a similar capacity in 1897. He was elected permanent secretary of the association at the Toronto meeting in 1898 and from that time until the close of the meeting in 1919 continued to fill that important office. His efforts in building up the association have succeeded in more than quintupling its membership and his many friends were glad to testify to their appreciation of his merits by the unanimous acceptance of his name for the presidency in 1919.



**Dr. Leland Ossian Howard, the new president of the American Association for the Advancement of Science**

## Plant Movement and Radiant Energy

THAT a sunflower will turn on its stalk sunward from dawn throughout the entire day is known to everyone; and that branches of trees grow more luxuriantly southward than northward, is a matter of common observation. Similar evidences of the heliotactic response of growing plants to radiant energy will readily occur even to persons not especially interested in plant physiology. On the other hand, the writer has found, by questioning numerous friends and acquaintances, that few persons who are not botanists are aware of the very active response of cut (detached) branches of trees, especially trees of the genus *pinus*, to radiant energy, whether proceeding from a common electric-light bulb or from the sun. In this connection, the following experiment, demonstrating the "motor-power" of these two manifestations of energy acting on plant cells may be of popular interest, since the phenomenon may readily be produced by anyone at will.

Place three or more stems and twigs of any "evergreen" species of tree (pine, hemlock, cedar, etc.) in a vase or jug, with or without water, and suspend the vessel by means of twine or ribbon from a shelf or a projecting "arm," so that it may move without obstruction, near a window with sunward exposure. Let the center of gravity of the overhanging twigs be somewhat away from the direct sunlight. It will then be seen that the sunlight will pull the green twigs, together with their container, away from the center of gravity, but that the pull is not sufficient to hold the plant in this position, and it will return almost immediately to its original station; but only to be pulled sunward again within a moment or two. The effect, then, is an almost continuous movement to and from the sunlight, with short pauses between; neither gravity nor radiant energy being competent to hold the plant still.

When evening comes, an electric bulb of at least sixty-watt power, placed even a few degrees on either side of the center of gravity, will produce the same constant swing to and fro. Tobacco smoke in the air seems to increase the arc of the plant's movement. The sap drying at last, the movement ceases; addition of water brings renewal of motion.

Now try to conceive the actual internal mechanism of this constant fluctuation produced by sunlight or electric rays. Is it *heat* that draws the plant toward the light? If this were the explanation, a sad-iron heated to the electric bulb's temperature would secure the same motion. Try it. Is the rhythmic movement caused by the "light"—does electric or sunlight *pull* a green bough when separated from the living tree? Light is not regarded as a substance, as matter, because experiment proves that darkness can be produced by the addition of two portions of light. Such an experiment is not possible with substances, as usually understood. How, then, can it attract, pull, these several twigs?

That light can push or repel matter is well known. Such a repulsive force was attributed to sunlight by Clerk-Maxwell (1870), when he propounded his electromagnetic theory of radiant energy; and this mechanical pressure was experimentally demonstrated and measured in 1901 by Peter Lebedew, and soon thereafter his work was carried forward by Nichols and Hull. The repulsive pressure of light has been fairly well explained. But how can the light force green twigs to turn (carrying the vessel) in its direction as against the pull of gravity?

Possibly some of the readers of this magazine can give an explanation of the phenomenon that will really explain. To say that the plant cells are *hungry* for the lumic energy necessary for the splitting of the molecules of carbon dioxide, so that they may, through the agency of the chloroplastids, feed on the atom of carbon in $CO_2$, building up the highly complex substance called starch, and are thus naturally heliotactic—is to state a fact rather than to explain it. Undoubtedly electronic forces are at work in the process, and somehow force the cells lightward; but how?

Leibnitz long ago pointed out that force, or the exhibition of energy, is the most important and fundamental phenomenon in the universe. That force we now know to be electric energy; but we do not yet know what electric energy is. We do know, however, to a certain extent, the conditions under which it becomes manifest to man's senses, and how it can be harnessed for man's uses. But we do not know how it is harnessed and utilized for the plant's uses. The energy hidden in the cell of a living plant, enabling it to convert the inorganic into the organic—into that enormously complex material represented by the formula $C_6H_{10}O_5$ —is at present quite beyond man's comprehension.

## Fire-Proofing Cotton

A PROCESS has been devised for treating baled cotton with a chemical compound which renders it flame and spark proof and at the same time apparently provides an inch or two of cotton in condition to aid in rapid drying without deterioration in case a bale is exposed to weather. On an average, 20,000 bales of cotton are destroyed by fire before the crop is marketed and most of this loss can be traced to flash or spark fire. Cotton stored in suitable warehouses would be evidence of a progressive step, for there is probably no crop of so great value that is treated with so little thoughtful consideration.

# Disposing of the Sewage

## A Typical Plant at Mount Vernon, N. Y., with Special Features of Interest in Overhead Distribution

By Sanford G. Plumb

1. Water test of the nozzle and inverted spraying disk for underflow distribution. 2. Rear view of filter bed sheds and tank discharging oxidized effluent into the river. 3. Overhead gravity distribution, with streams of sewage falling on spraying disks

**How Mount Vernon takes care of its sewage to such good effect that it does not seriously pollute the river into which it is discharged**

UNTIL the plant at Mount Vernon, N. Y., was built, no system for sewage disposal using the overhead distribution by gravity had ever been installed. This system had been developed at the sewage experiment station of the Massachusetts Institute of Technology, and it was on the basis of the satisfactory results here indicated that it was adopted by Mount Vernon, in connection with the disposal of sewage from the more elevated parts of this decidedly hilly little city. For the lower sections of the town, the sewage enters the works in the usual fashion, 26 feet below the level of the screen chamber and septic tank, and is brought up to that level by two electrically operated pumps of 25 horsepower each. The total volume thus handled is 1,000,000 gallons; to this the gravity system adds 1,500,000 gallons. The combined mass flows through the screen chamber and septic tank to the overhead distributing system of pipes above the filter beds.

On the satisfactory results obtained at Mount Vernon has hinged the adoption of this system of sewage distribution in several other cities; and for this reason the Mount Vernon plant is the scene of frequent inspections by officials from other States. The plant has been in successful operation eleven years, which should be sufficient to establish the principle as a sound one.

As an introduction to the subject, we may say something of the theory of sewage disposal by trickling, borrowing the subject matter from Metcalf and Eddy on Disposal of Sewage. Liquefaction, the change of insoluble substances into soluble ones, has been described as a result of bacterial activity through enzymes. Certain species of bacteria appear to liquefy in a much greater measure than others; the aerobic bacteria are reinforced by enzymes. The process of oxidation of free ammonia, first to nitrites and then from nitrites to nitrates by separate and distinct organisms, is called nitrification. That nitrification is due to bacterial action is apparent from the fact that it is checked or stopped entirely by low temperature, by heating to the point of sterilization, and by certain chemicals inimical to the life of bacteria. Furthermore, temperatures favorable to bacterial development cause nitrification to proceed rapidly.

While some enzymes have been known for years, even before the organisms secreting them were known, there is still no knowledge of their chemical composition. They possess the peculiar property of not being destroyed by the process in which they take part. Like the organisms which secrete them, they are sensitive to heat and poisons, becoming inactive on exposure to temperatures about 50 degrees to 80 degrees C. and to disinfectants like formaldehyde and mercurial chloride. The final decomposition, the process which yields the energy for cell life, must take place within the cell. Investigations of recent years demonstrate that these processes are caused by enzymes.

The trickling filter is capable of converting putrescible settled sewage into stable effluent, not subject to putrefaction under the most exacting conditions. In trickling filter-beds, the sewage is applied to the surface as uniformly as possible by sprinklers or other devices. Experience has demonstrated that usually the trickling filter-beds are self-cleansing.

The settling solids not removed by preliminary sedimentation are retained mechanically in the pores of the filters. The colloidal matter adheres to the surfaces through attraction and absorption and the dissolved organic matter is absorbed by the bacterial jelly or acted upon directly, probably both processes occurring. The bacterial jelly coats the stones from top to bottom of the bed, in mature condition, and appears to perform its functions in relays, that at the top acting upon so much of the organic matter as its capacity will permit, that of the next stratum below attacking the substances passing by the upper one, or perhaps emitted from it, partly oxidized, and so on to the bottom, where the oxidized sewage falls through the floor grating into the underground drainage system, the organic matter being converted into humuslike material or resolved into carbon dioxide and other soluble and gaseous products and the nitrogenous substances being oxidized with products of ammonia, nitrites and nitrates.

Knowledge of the particular organisms present and the work which each species does is lacking, but it is certain that the processes are chiefly aerobic, for failure to supply air is quickly reflected in the inferior quality of the effluent.

The periodic storage and disgorging of solids by the trickling filter is one of its most important and interesting features. When sewage first reaches the public sewers, it is "fresh" and contains free oxygen, so that aerobic bacteria thrive. The bacterial activity rapidly depletes the oxygen, which may become exhausted, as sewage, unless vigorously agitated, absorbs oxygen from the atmosphere very slowly. After a lengthy flow through sewers, aerobic bacteria, though present, are fast losing their activity. Such sewage is classed as "stale" and at the same time the faculative anaerobes begin to increase in number and activity.

The depletion of oxygen is particularly marked if the sewers are of such length that several hours elapse before the major part of the sewage reaches the outlet. Soon the last traces of oxygen disappear, the sewage becomes very dark, or even black, and hydrogen sulfide or other sulfides are formed.

When sewage stands for a long time or flows very slowly through tanks, the anaerobic organisms gain the ascendency and ammonia, marsh gas, carbon dioxide, hydrogen, nitrogen and other gases may be formed, as the complex organic compounds are broken down into simpler ones. This is a reduction or septic process.

While oxidation goes on to some extent during anaerobation, it is usual to consider aerobic conditions essential to oxidation which approaches completeness. Oxidation of organic matter is effected by many aerobes, including those producing nitrites and nitrates.

It will be deduced from the generally accepted theory so concisely expounded in the foregoing extracts not only that an even distribution of the liquefied sewage over the surfaces of the filter-bed is essential so as not to flood the interstices, but that it needs to be violently agitated to renew the supply of oxygen by aeration; hence the importance and signifi-

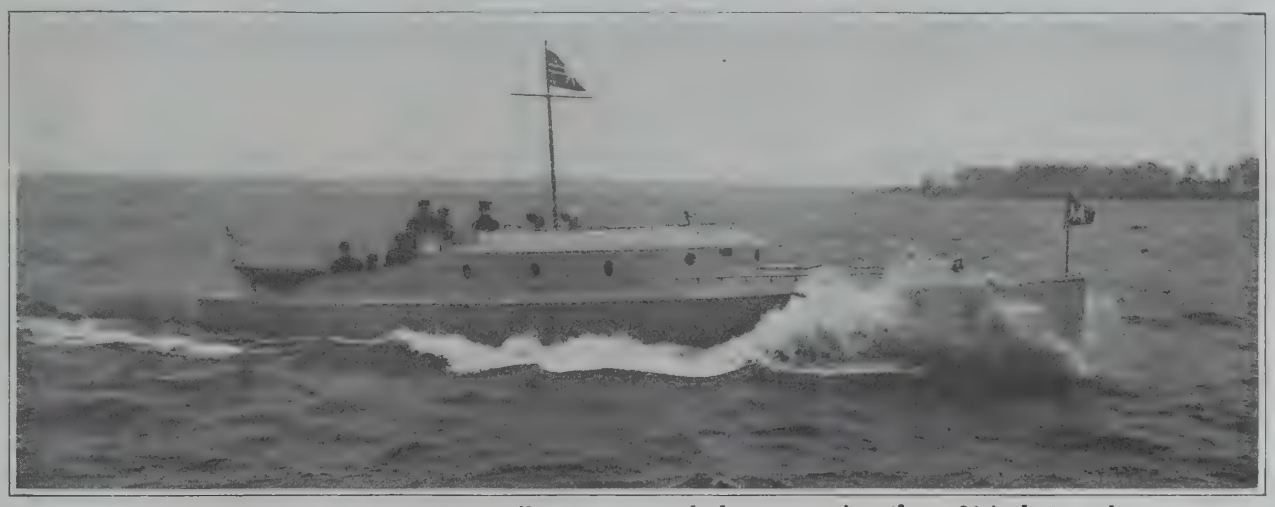
## A New Type of Torpedo Boat

IT is an interesting study to trace the profound changes which important successive engineering developments have produced in the design of naval ships, changes which in some cases have been distinctly of a revolutionary kind. Particularly is this true of motive power. The advent of the practical marine steam engine stripped the fighting ship of its towering fabric of masts and sails, and so greatly increased the maneuvering power and speed of the warship that the picturesque frigate and three-decker disappeared from the seas forever.

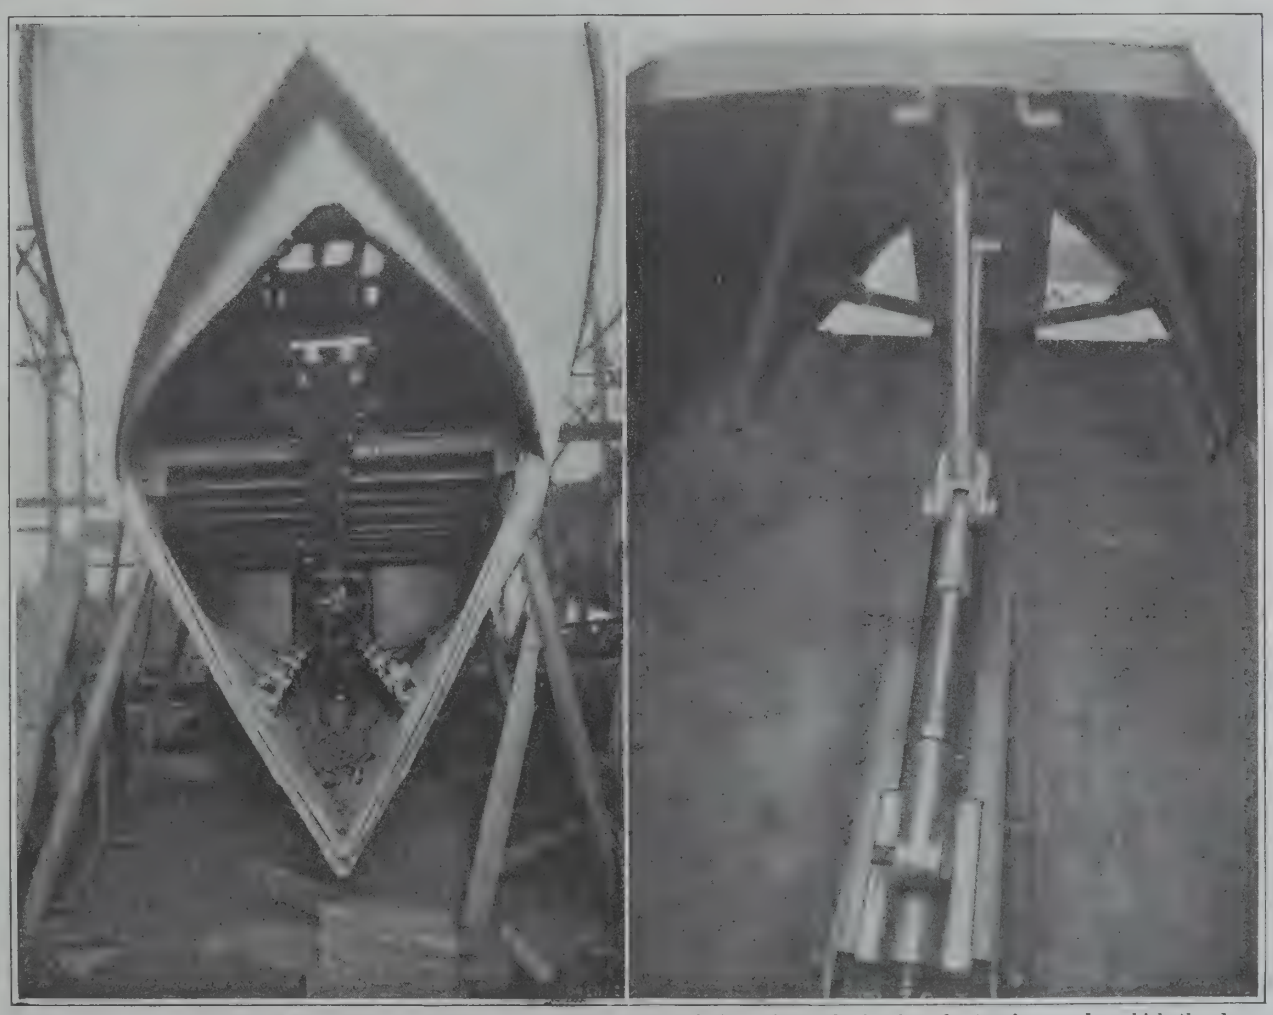
Similar in kind, though not in degree, are the changes which have been wrought by the introduction of the internal combustion motor and the use of oil fuel. As steam power reduced the visibility and increased the speed of warships, so oil fuel and the oil engine are reducing the visibility of warships by getting rid of telltale smoke and rendering possible a marked increase of speed in the larger ships and a phenomenal increase of speed in the smaller craft.

It was only a question of time when the high-speed motor boat would begin to attract the attention of the naval designer and lead him to seek some way in which he could utilize in naval craft the astonishing speeds achieved by this type of boat. The official speed of 70 miles an hour, maintained by "Miss America," in the recent contests for the Harnsworth cup, was the culmination of motor boat speed, which had been advancing by leaps and bounds during the past ten years; and it was inevitable that a serious effort would be made to utilize a modified form of motor boat in those fields of naval warfare in which a combination of invisibility and high speed is of prime importance.

The accompanying illustrations represent a most promising effort in this direction. The boat is the product of civilian effort, and it is the third of its type to be built by its inventor, Mr. W. B. Shearer of this city. One of these illustrations was taken a few minutes after the boat had been christened by the wife of the inventor and launched on the Sound at City Island, in the presence of a party of guests consisting mainly of ranking officers of the Army and Navy. As soon as the little craft was clear of the ways, the engines were started and she went through a number of evolutions at speeds of 15 to 20 miles an hour. Because of the fact that the engines were new, no attempt was made on these tests to reach the maximum speed of 32 miles an hour. The dimensions of the boat are—length 58 feet and beam 9½ feet. The twin engines develop 600 horse-power. The "Sea Hornet," as she is called, was designed to meet the conditions which the inventor considers to be indispensable for successful torpedo attacks, namely, small size, invisibility, high speed of approach and retreat, and mass attack.



The "Sea Hornet," a 58-foot, 30-mile motor torpedo boat, carrying three 21-inch torpedoes



*Left:* View of bow, with the torpedo firing chamber open. *Right:* View looking forward, showing the toggle gear by which the door of the firing chamber is opened when firing the torpedoes

**Details of the torpedo-firing mechanism of the motor torpedo boat "Sea Hornet"**

In spite of the high stage of development to which the torpedo has been brought, and the great range which the latest types can cover, the experience of the late war has shown that to hit a ship at ranges of 7,000 yards and over is more a matter of luck than good shooting. In the great battle of Jutland, torpedoes were discharged by the hundreds; but the percentage of hits was exceedingly small. The explanation is to be found in the impossibility of close approach by destroyers, because of the destructive fire of the heavy anti-torpedo batteries carried by the modern battleship. To make sure of a hit, torpedo craft should approach to within 1,000 or 2,000 yards range, something which is impossible for the modern destroyer, which is a big ship, 1,200 to 1,500 tons in displacement and over 300 feet in length.

The "Hornet" with its speed of 30 knots and over would make its rush for the enemy end on and in great numbers (it can be built for $30,000 to $40,000), and so low do the craft lie in the water, and so great would be the change of range as they approached, that it would be impossible for the gunners on the enemy ship to change and set their sights quickly enough to make sure of a hit. Even were a barrage laid down, the boats would be so quickly through it that the chances of disablement would be small.

A remarkable fact in connection with these little craft is that they can carry three of the largest 21-inch torpedoes, which are carried upon bronze rollers bolted to the floor of the boat. The first torpedo is carried in the firing chamber at the bow; the second is below and between the twin engines; and the third below the deck of the cockpit, each being in its own separate watertight compartment. In firing, a large valve is opened and the bow compartment is flooded. By means of a threaded shaft connected to a powerful toggle gear, the lower half of the bow swings up and back and houses within the boat. The starting lever of the torpedo engines is then tripped, and the torpedo leaves the bow under its own power. Two powerful pumps then clear the firing chamber of water, and the second torpedo is pushed forward into the chamber ready for a second attack.

Motor torpedo boats open up a wide field for the use of the torpedo. They can be carried on special motor-boat ships corresponding in size and speed to airplane carriers, which would accompany the main fleet, the boats being launched for mass attacks on the enemy's battle line. They would form a valuable auxiliary to our coast defenses. As matters now stand, a great increase in the range of naval guns has put the larger part of the artillery of our coast defenses at a serious disadvantage. When these fortifications were designed and equipped, naval ranges were less than one-half what they are today; and it would be possible for a fleet of modern ships to lie at a range entirely beyond the reach of a large portion of our shore batteries, and bombard them without the batteries being able to make any reply. It is considered that the maintenance of flotillas of these motor torpedo boats at or near our principal coast fortifications would effectively prevent any such long-range bombardment, since they would effectually break up the enemy's line and render it impossible to carry out any accurate and sustained attack.

## An Explanation of Leaning Chimneys

BETWEEN the wagon builder, alternately wetting and drying a board to bend it to the desired shape, and the house chimney, grotesquely leaning toward the east, brick masons say there is similarity. The leaning chimney is a subject on which even the doctors disagree, but the theory referred to seems the most plausible.

Chimneys lean toward the east. A little observation anywhere will prove this. Even the best-built affair of brick and mortar, acquiring age, often begins to lean. Various theories are advanced, but the explanation of alternate wetting and drying seems the best.

Chimney walls collect more or less moisture during the night, on all sides. Now if the broad side of the chimney is toward the east, and if the sun strikes that part of the chimney first, as it will, that side dries out much quicker than the north or south side, or the western side. In time of rainfall, the east side ordinarily is dried the quickest. This general condition has the effect of pulling the chimney toward the east.

# A New American Industry

## How the Making of Toys Has Been Established on a Solid Basis in This Country

By Harry A. Mount

WITH foreign-made toys again available to American buyers and prejudice against the "Made in Germany" mark fast disappearing, what is to become of the American industry which sprang up overnight in 1914? For the first time since the war our toy makers are beginning to feel the effects of competition. Several of the mushroom concerns already have been forced out of business. But the industry as a whole, investigation reveals, is well intrenched against competition from foreign lands and undoubtedly will survive its crucial test. The war has added a new American industry.

Before 1914 about ninety per cent of the toys sold in the United States were made in foreign lands. The ten per cent of American toys sold were, as a whole, an inferior product. Toy sellers thought of games in terms of Spear, the one great German toy house. The highly colored and exquisitely finished German games had no American rival. The finest dolls came from Germany and France and mechanical toys were almost certain to bear the German trade-mark.

Today our games are as good as any that came from Spear; we are making better dolls than ever came from abroad; and our mechanical toys are far superior to the foreign product. It was once the habit of American toy-buyers to make a mid-summer trip to Europe to order toys for the holiday trade. For the last five years these junket trips have been cut off. Undoubtedly much of the foreign ordering now is being done by buyers who are more anxious to see battle-scarred Europe than to find better toys than they can secure at home. But American manufacturers are not asleep. They are already shipping thousands of dollars worth of American toys to Latin-America, which once was supplied almost entirely by Germany. They are even selling toys in England and France and at least one firm is shipping dolls to Berlin.

But why are American toys the best in [illegible] today?

The toy industry naturally falls into three distinct divisions and it will be necessary to consider each independently. The largest-selling toy line is dolls. That is because dolls, as miniature reproductions of our own selves, have the most universal appeal. Every girl must have her family of dolls, but boys too play with them and even men and women buy thousands of dollars worth of novelty dolls each year.

The first requisite of a good doll is a beautiful face, with the texture and fine coloring of a real head. German bisque heads came nearest to perfection in former days and bisque dolls were standard. When the supply of German dolls was suddenly cut off there was a demand for dolls which existing American manufacturers could not begin to supply. As a result small cloak and suit makers and a variety of similar manufacturers turned their establishments into doll factories. They made very creditable cloth bodies but in attempting to supply heads the American makers "fell down" flatly. They failed to recognize that it is the beautiful child's face which makes the appeal in a doll. Artists of indifferent ability were engaged to model the heads, poor clay was used for the bisque, bad colors were used. The first flood of American dolls was therefore very disappointing.

But out of some 125 doll factories that sprung up to meet this new demand, a few have recognized that doll making is a fine art and their success more than compensates for the first poor results. German practice has been discarded and the doll you buy today for your little girl is a thoroughly American little miss. Her head is not of brittle bisque but is of a non-breakable composition. The texture of the finish and the coloring, however, are just as fine as that of the German bisque. The bodies are of the same material or are of cloth stuffed with ground cork, but in either case they are more substantial and better made than the imported bodies. Both bodies and head have been designed by the best artists to be found. The faces no longer present the blank, staring "baby-doll" look, but real character is graven in them. Probably the best selling doll in the world today is modeled after a famous cartoonist's conception of a real little girl. She doesn't wear just a one-piece dress of cheesecloth, but her clothes are designed and made just as carefully as if she were a real little girl.

There are several compositions and processes for making dolls but the one most widely adopted consists of pressing a mixture of sawdust, resin and glue into hot molds, producing half of the head or body. The two halves are then glued together, baked, trimmed, dipped in specially prepared enamels and finally finished by artists.

And so while the American doll makers are apparently losing ground just now because many of the small factories are closing, the foundation for a distinctly American doll industry has been laid and no foreign country at present is able to compete with the product.

Next to dolls in appeal in the toy line are the games. Two or three American game makers have been long established, but it must be frankly admitted that their product had failed to reach the degree of excellence obtainable from foreign makers.

These factories have doubled and tripled their output since 1914. But they have done more than that. They have been searching for better manufacturing methods, better colors, better materials, better designs and as a result their product is just as good today as the finest to be obtained elsewhere. Added to this are American methods of quantity manufacture so that in the United States our game manufacturers have every advantage over foreign competitors. There seems little chance that American games will ever be superseded where they have gained a foothold and their selling range is being constantly widened.

The third line, mechanical toys, is most firmly established of the three. The foreign-made toys were brightly colored and finely finished, but very frail. The mechanisms were poorly designed and once broken they could seldom be repaired because parts had to come across the sea.

Take toy trains, for instance. Nearly all of these were imported before 1914. Now there are two American makers whose products have come to be the world standard. Not only are the trains they produce just as finely finished as any others, but they are built with the precision of real trains, with well-designed and robust mechanism. Parts for these trains are quickly available.

Sheet-metal toys which formerly were made in Germany have been re-designed and the American-made toys look just as well and are much stronger. Yankee

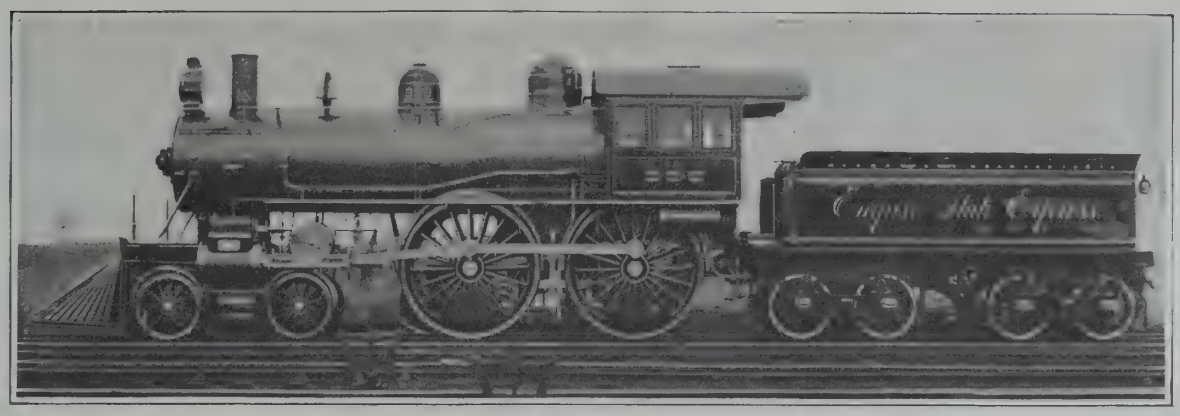
## Old 999 Still in Service

**By Ralph Howard**



**Engine 999 as she appeared in her heyday, when she hauled the Empire State Express at a net running speed of sixty miles per hour**

CONSIDERABLE circulation was given, recently, to a statement that No. 999, the famous engine that hauled the Empire State Express for so many years, had been sent to the Port of Missing Engines, otherwise known as the scrap heap. This is not in accordance with the facts, for the famous locomotive is still in service on the railroad that it helped to make famous. In this connection the New York Central has supplied us with material on the history of the old engine, which many readers will find of great interest.

No. 999 was built entirely at the construction shops of the railroad in West Albany. She was completed in 1892, and went into regular service in front of the Empire State Express early the next year. Built for light, fast running, she was ideal for this light, fast train. She was equipped with special 81-inch drivers and 40-inch truck wheels, and was the first engine to have brakes applied to her front trucks. It was with her doing the hauling that the train made its much disputed record of 112.5 miles per hour. The scheduled time for the 439 miles run between New York and Buffalo was eight hours, with four stops. Deducting all stops, etc., the schedule called for a net speed throughout the run of just about sixty miles per hour. Owing to heavy traffic and other conditions, these exacting demands on the Empire have been modified, and her schedule now allows her nine hours to make the run.

It is to be emphasized that, while engines today are built much heavier than the 999, their drivers are not so large. This puts them at a double disadvantage when it comes to a question of pure speed; for not only must a greater piston speed be developed to cover the ground at the same rate, but the pounding on the track is vastly greater. The engines of today will make their maximum speed with a far longer and heavier train than their predecessors of twenty years ago—the 999 would not begin to make 60 miles per hour with nine or ten cars; they would make just about as good speed as the old fellows did, in fact, if the track were such as to permit it; but if we attempted to run the Empire State Express of today at any such speed as 100 or 110 miles per hour, the first curve would probably see her ditched by spreading rails. Her limit is about 80 or 85 miles on the straightaways.

After about twenty years of service of the sort for which it was built, it became necessary to retire the 999 from the main line, in recognition of the length and weight of the through trains of the new period. The famous engine was therefore shifted to the Rome, Watertown and Ogdensburg, then maintaining its operating organization more or less distinct from the big line but now known merely as the St. Lawrence Division. In 1913, after considerable alteration, her number was changed to 1086. Soon after she was shifted to the Pennsylvania Division, where she has been employed ever since, and where she is now rounding out her twenty-ninth year of active passenger service.

A glance at the record card of the old locomotive is of interest. It appears that her original cost was a mere $13,000, and that in the last thirteen years of her career she has been the beneficiary of thirteen more or less general overhaulings at a cost of some $14,000 more. This phase of her record cannot be given for her complete career, since repair sheets prior to 1908 are not accessible. The time when the famous old locomotive is no longer available for service is remote, but when it arrives, plans already under consideration will insure her an honorable post of retirement and exhibition in the Grand Central Terminal at New York. This will be a fitting terminus to the history of an engine that has contributed so largely to the railroad lore of the United States.

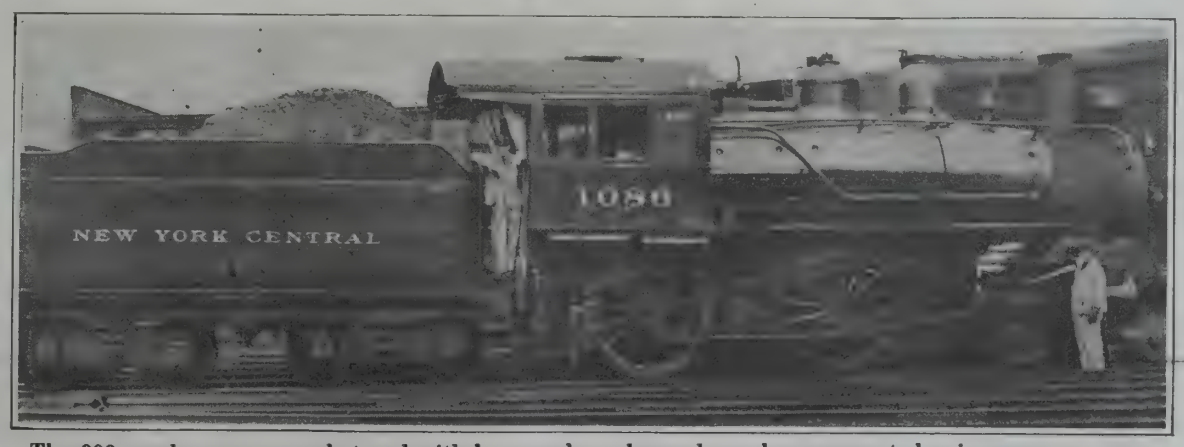
**Scraping off the coal in the open mines of the Nieder Leustiz district of Germany, by means of a giant scraper which delivers the coal into the coal cars.**

Copyright, Keystone View Co.

## Coal Mining in the Open Mines of Germany

COAL generally calls up a vision of dusky miners working far down in the bowels of the earth, laboring hour after hour in cramped quarters and faced with all sorts of danger. So the accompanying view of the activities at the open mines of the Nieder Leusitz district of Germany is of more than passing interest, because it shows one phase of coal mining that is utterly different from the accepted version—as different from conventional coal operations as the iron mining of Michigan is distinct in its field.

These barren coal mines of Germany make mining a simple matter. By means of shovels of the type here shown, the coal and admixture of dirt is scraped off the surface and loaded directly into coal cars on top of the embankment. These cars transport the coal and dirt to the plant where the larger coal is sorted out from the similar pieces and the dust, the latter being compressed into briquets.



**The 999, made over somewhat and with her number changed, as she appears today in passenger service on the Pennsylvania Division of the New York Central Lines**

## The Properties and Uses of Manjak

THE term "manjak" is applied to a variety of bitumen or solid hydrocarbon occurring on the Island of Barbados, and in Utah, Cuba, and Trinidad. The deposits on the latter island are found within a distance of three miles of San Fernando, the second largest town on the island, and within three miles of the famous asphalt lake.

In chemical composition, manjak is like asphalt. It is almost pure bitumen. Its melting point is, however, more than 400° Fahrenheit, whereas asphalt melts at 100°. In composition, it consists of 80 to 90 per cent carbon, the balance being chiefly hydrogen, with a small quantity of sulfur. It resembles coal in appearance, is odorless, hard, and brittle. It is found in thin beds between layers of clay.

The island of Trinidad is rich in this mineral resource. Its development has as yet hardly begun, and the exportations already made have been with the view of testing out the material. During 1918, exports to the United States were valued at about $3,100, and in 1919, up to October 1, they totaled 41 tons, valued at $1,900. Prior to 1900, manjak was mined on a small scale in Trinidad, but for various reasons, very little was done between 1900 and 1913. In the latter year, mining operations were resumed, and at the present time there are five shafts, one of which has reached a 37-foot bed of manjak at a depth of 400 feet. Operations could be greatly extended if there were a greater demand for the material.

It has not been found profitable to export manjak from Trinidad in the crude state as the price received, namely, $37 per ton, hardly covers mining expenses. These are increased by the necessity for careful and thorough timbering on account of the clay formation.

Compounds, made by combining manjak with mineral oil, command fair local prices which have enabled mine operations to proceed at a profit. Experimentation is still in progress with different mixtures of manjak and oil for various purposes. The manjak recently sent to the United States was for the purpose of ascertaining whether American oils would be more economical and useful for mixing with the manjak than the Trinidad oils. It is the plan to erect a plant very soon for the manufacture of manjak paints and compounds.

Manjak is rapidly increasing in use, according to the U. S. Bureau of Mines, particularly in connection with the oil industry. It is produced in close proximity to the oil wells in Trinidad. It is boiled with oils at high temperatures and converted into compounds and paints for nearly every purpose where a preservative is needed, for example, on pipe lines, boilers, chimneys, and miscellaneous iron ware, machinery, etc. It is usually applied in the liquid state, hardening into a tough, rubberlike coating. It has low viscosity, and is not affected by ordinary heat. It makes an excellent insulating material and is impervious to both air and water. In hot and damp climates, like that of Trinidad where pipe lines quickly deteriorate, their life has been prolonged for extended periods when painted with this material.

The most important use of manjak, and one wherein it has won a reputation for saving money, is in connection with rotary drilling for oil. A soft compound is used on the joints of the pipes between the casting threads and drill stem threads, and this prevents either water, sand, or grit getting into the threads, thus preserving them from being stripped or worn off. It not only acts with partic-

# With the Engineers of Industry

## *A Department Devoted to the Physical Problems of the Plant Executive*

*This department is devoted to business men, works managers, production engineers, and all other executives seeking the maximum efficiency in carrying on their work. The editor of this department will endeavor to answer all questions relating to plant equipment, factory management, and industrial affairs in general.*

### Ventilation Made to Order

IN keeping with the steady trend toward specialization in all the arts and sciences, ventilation has become a highly specialized branch of engineering. And happily so; for the subject of ventilation is one of vital importance where the general health of the workers and their general efficiency are matters of prime consideration.

Time was when ventilation was merely a matter of opening the windows and doors more or less to admit the necessary amount of air from the outside. During extremely cold weather the windows and doors were kept tightly closed, because the admission of fresh air also meant the admission of cold. As a consequence the air in such plants became quite vitiated in the course of the working day, and the workmen became drowsy, careless and inefficient. It was inevitable.

Perhaps the best proof of the value of proper ventilation is to be found in our modern theaters, where ventilating systems handle a tremendous amount of fresh air while the shows are in progress. In one of the recent installations of this sort, in a theater seating 5,500 persons, the air is changed every few minutes. Huge blowers take in fresh air and pass it down through the outlets in the ceiling and under the balconies, while smaller outlets scattered about the floor line remove the foul air. During the winter months the air is heated by passing it through steam coils, while in summer the volume of air is considerably augmented so as to lower the temperature within the theater. By exhausting somewhat less than the amount of incoming air, it is possible in cold weather to build up a static pressure, so that when doors are opened there is absolutely no rush of air into the room. In some instances something like 75 per cent of the air is exhausted through the regular outlets, leaving an excess of 25 per cent which percolates through doors and other openings and prevents draughts.

The ventilating systems now being installed in various kinds of buildings are worthy of serious consideration, since they make for the utmost efficiency. For one thing, most ventilating systems may be made to heat the largest room by passing the air through heating coils. This method of heating is highly efficient, since it keeps the heat in constant circulation. All in all, the subject of ventilation is an important one and should be considered. But before taking any action in this direction the plant executive should first consult the engineering department of the various manufacturers of blowers and other ventilating equipment. Remember, they are specialists!

### The Value of Clean Floors

IN a previous issue we had something to say about clean walls and their effect upon the morale of the workers. Now we have something to say about clean floors, which also react on the morale of the workers. Furthermore, clean floors have a certain advertising value in such plants as welcome visitors. Nothing makes for an impression of efficiency and pride in self and in product as does a clean floor.

To the end of simplifying the scrubbing of large floor areas, especially the concrete, stone or tile floors of the factory, office, theater entrance or hotel lobby, a number of electrically-operated scrubbing machines have been placed on the market during the past few years. These machines are all of a more or less similar design, consisting of a fractional horse-power motor driving an arrangement of stiff brushes in contact with the floor, and storage tanks for soap and water. A reel mounted on the wheeled cart carrying the scrubbing equipment, pays out wire as the scrubber is pushed over the floor. Any workman can scrub a large area of floor space in a short space of time with the electric scrubber. The physical exertion is practically nil. Furthermore, the scrubber produces a better job and more uniform work than can ever be done by the manual method of scrubbing. And it goes without saying that the cost is far below that of the back-breaking method.

Whether or not to use an electric floor scrubber is merely a question of the amount of scrubbing to be done. Just as it would not pay a gardener to use a gasoline tractor for cultivating his flower beds, so it would not pay anyone to use an electric scrubber in a small shop, store, office or other place. It is a question of volume of scrubbing.

### The Steel Fence Investment and Its Returns

THE day of the wooden fence about the plant is gone. Wooden fences have outlived their usefulness. They never were highly satisfactory, but for want of something better they continued in use until the advent of the present steel-post, wire-netting and barbed-wire fences.

The various systems of steel fencing are more or less designed along the same general lines. They consist of various styles of steel posts which are set directly in the ground or are imbedded in concrete, and stout steel netting. Fences of this kind protect the plant against trespassers, thieves, firebugs, and other undesirables. Indeed, the steel fence is so secure that it virtually extends the storage space of the plant buildings beyond their walls, since the yard becomes just as secure as the store rooms, as far as theft and fire are concerned. It also protects the workmen against accident by preventing their crossing dangerous railroad tracks, taking reckless short-cuts, and so on. It simplifies the handling of workmen, since it limits their entry and departure from the works to certain definite gates. All in all, the steel fence marks a big step forward in plant efficiency, both from within and without.

### Motor Drive for Operating Sashes

THE large number of sash units to be handled in many of our plant buildings has caused the introduction of motor-operated devices. The "runs" that are handled by the electric motor installation may be as great as 600 feet, consisting of a system of shafting, cables, rods and arms, counterweights and spirals, actuated by a single motor.

One system of sash operation which has met with wide favor makes use of counterweights and spirals, acting through the transmission rods and supporting the weight of the sash when open, thereby relieving the worm gearing and motors of that load. By requiring the motors only to overcome friction (and that a minimum), from 500 to 600 feet of 6-foot sash can be operated with one smaller motor. Without the spirals and counterweights, claim the designers of this system, four motors would be necessary here; or the motors would have to be much larger. Another advantage of this particular system is the uniformity of the load. Adding a spiral and counterweight makes it easy for the motor to restart the sash when stopped partly open, and gives uniform operating conditions, including speed and wear, for all points from shut to open.

### Some Gasoline Precautions

IN gasoline engine installations and where gasoline is stored, it is almost impossible to prevent slight leaks in the gasoline system, causing the oil to leak out and gasoline vapor to be formed in greater or less quantities. This alone will cause gasoline vapors to be present more or less continuously, especially in the lower spaces under subfloors, floor plates, etc. The danger of the spark necessary for the explosion is always existent and cannot be wholly eradicated. Under these conditions it is of the utmost importance to prevent the accumulation of the vapor in sufficient quantities to form an explosive mixture.

According to A. S. Baker, Plant Protection, Philadelphia Navy Yard, writing in *Safety News*, this can be done by proper ventilation, which can be accomplished by the installation of suction fans near the floor, or between the floor and the sub-floor if any exists. This fan should be run at least one hour daily and in addition at such other times as the presence of gasoline vapor is suspected or is liable to accumulate. In the small private garage, a small space cut out at the base on both sides will be sufficient to carry off this vapor.

In addition to the above, gasoline should not be used for cleaning in enclosed spaces if its use can be avoided. Take the articles to be cleaned to the open air and clean them there. However, where it is necessary to use gasoline or gasoline rags for cleaning in enclosed spaces, use only small quantities in a stoppered container, and see that the smallest possible amount is exposed to the air at one time. Also have as much ventilation in the room as is possible. Avoid rubbing or striking objects liable to generate a spark or static electricity. A good plan is to shut down all electric appliances or machinery in operation in the vicinity. Prohibit all open flames of any description in the immediate or near vicinity. Oily waste or rags should at all times be placed in a safe receptacle to avoid danger of spontaneous combustion. Empty gasoline containers should be filled with water and stored in safe places in the open air.

To extinguish a gasoline fire, one of the several leading types of fire extinguishers should be used. Sand may also be used if available, as well as a mixture of sawdust and bicarbonate of soda; even a wet blanket may be used in the case of a small fire, to smother it. Water should not be used, as the gasoline will float and the only result will be to spread the extent of the fire. There is, however, one case in which water may be used to advantage, viz.: Where gasoline floating on the surface of a stream becomes ignited, hose streams may be used simply as brooms to sweep the flames away from docks, boats at anchor or tied up at the piers, or buildings along the water's edge, which may be endangered.

### Soot and the Boiler

ANYWHERE from 4 to 10 per cent of the fuel used under a boiler in the usual way may be saved by the use of soot blowers, according to fuel engineers. When soot accumulates on the heating surface of a boiler, it builds up a greater or less layer of heat insulation between the boiler and the fire, thereby diminishing the efficiency of the fuel to just that extent. For it is obvious that a large part of the heat is lost because it is not transmitted to the water; and this means excessively high coal bills, and poor, uncertain service from the boiler. Obviously, too, high efficiency in the generation of steam is dependent upon the maintenance of the cleanest of clean heating surfaces.

A hand lance is often employed to clean the soot from the boiler's heating surface, but this method is a relic of past days of relative inefficiency. Such a method is all well and good in the case of small boilers, where the saving effected by an automatic installation would hardly offset the cost within a reasonable period of time. But in larger boilers the soot blower means a material saving in fuel costs, in some instances as high as 10 per cent.

### Keeping the Sprinkler System from Freezing

SPRINKLER systems should always be in good working order, ready at a moment's notice to protect lives and property against the ravages of fire. Under no circumstances should the water supply for the sprinkler system be allowed to freeze, for that defeats the entire purpose of such an installation at a time when fire risks are perhaps greatest.

It has remained for a manufacturer of water heaters to develop a satisfactory method of preventing the freezing of sprinkler systems. A multi-copper-coil gas water heater attached to the standpipe of any sprinkler system is said to make the latter absolutely freeze-proof. All through the long winter months it will automatically control the temperature of the water and keep it above the freezing point. The same system of heating may also be used for providing hot water for factory lavatories.

### Faster Rehandling with Less Labor

A HAND-OPERATED hoist is the means of effecting a material saving in rehandling costs, but an electric hoist effects just as great a saving again over the hand-operated type. Small electric hoists are finding wide application in many plants, both indoors and outdoors, where they are reducing to a minimum the cost of the necessary, but usually unproductive, item of rehandling. Electric hoists are generally mounted on wheels which travel on overhead rails. Two rope controls are provided, one for lifting and the other for lowering.

The latest German art — trimming shrubs to represent animals

## A Sculptor in Shrubbery

THE people of Germany are turning from war to art and pleasure. Their new art, with which we are particularly interested in this case, takes various forms such as exceptional publicity methods, odd store fronts, remarkable architecture, and bizarre landscape gardening.

The German gardener depicted in the accompanying illustration specializes in hedges surrounding large estates. He trims the shrubs in various ways so as to represent men, animals, geometrical figures, and so on. Obviously, this work calls for no mean ability in the manipulation of the shears not to mention an artistic temperament of a more or less creative type.

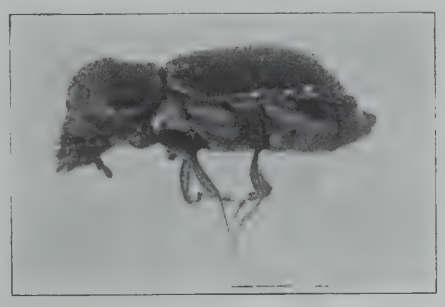
It should not be believed that the Germeans have invented anything new, as the art is quite old in England where it is known as the "topiary art," and whole books have been devoted to it.—By *A. M. Krumm.*

A simple ladder for climbing up to the bulb of a lamp post

## The "Short-Circuit" Bug of California

A WOOD boring beetle in California has found out a new way to add to the grief of the poor telephone girl. *Scobicia declivis*, for that is his only name, bores right through wood and alloyed substances which are considerably harder than lead. By boring holes in telephone cables he is putting hundreds of telephones out of commission; for when a chance rain comes along the water gets in the holes and right away somebody has a job trying to find out where the beetle has been working again.

The damage most always occurs where the cable is in contact with the ring by which it is suspended. Experimental work is being carried on with various types of suspension rings, lead alloys and chemical substances to cover the lead sheathing in order to prevent the ravages of the beetle. No practical method of control has been found yet.—By *Allen P. Child.*



The "short-circuit" bug of California, magnified about 7 diameters

## A Ladder for the Outdoor Lamp Inspector

AN inspector employed by the Harbor Board at San Francisco has devised a light ladder that he uses in climbing the lampposts along the water front for the purpose of replacing bulbs. Formerly it was necessary for the inspector to carry a large ladder from the nearest dock—a large ladder is kept in each dock for various purposes; but the new ladder, which only weighs a few pounds, is now carried by the inspector on his trips.

The new ladder, which the inspector carries without trouble, is provided at one end with a hook that is hooked into the scroll work at the top of the lamppost. The other end is strapped to the base of the post about 3 feet above the level of the ground. This eliminates the possibility of a motor truck striking the ladder and pulling the inspector from the lofty post.—By *C. W. Geiger.*

## An Interesting Drainage Culvert Constructed Through a High Railway Fill

DRAINAGE operations in Yakima County, Washington, are mainly for the purpose of reclaiming waterlogged land and areas on which alkali has accumulated through the lack of proper under-drainage or outlets for waste irrigation water. In the work of installing a drainage outlet for 10,000 acres of land in the county a culvert 100 feet in length in a 41-foot cut under the Union Pacific Railway, near Granger, had to be constructed.

In constructing the culvert piles of 65-foot length were driven through the center portion of the fill in order to reduce vibration from passing trains and protect the construction work itself. As the excavation progressed sheeting was placed behind the piles and cribs were constructed on either side. Material was removed by shoveling into steel dump cars which were run on a track to the end of the cut where the boom of a dragline excavator raised them and dumped the contents on the right-of-way.

Lagging was hand-driven to the lower lift, where volcanic ash, which is practically quicksand, was encountered. Water jet was used here and lagging was put into place by hand. Double lagging was necessary in order to prevent the water diverted through an old culvert from breaking through into the excavated area. The old culvert was 25 feet from the center line and 6 feet above the bottom of the culvert under construction. During the excavation of the last 8 feet a 5-inch and a 4-inch pump operated by electricity were used in diverting the water.

In the soft earth in the bottom of the trench gravel was placed considerably deep and on top of this a foot of concrete was laid. Concrete pipe, reinforced, and 4 feet in diameter, was placed on the concrete floor and the joints were cemented. Afterward a cradle of concrete was formed around the pipe where it lay.

## The Miniature Road Rollers of Belgium

BELGIUM is beginning to feel on her higways the strain of the motor truck. The roads on her national system are almost entirely of stone block laid on sand and sand-jointed. On account of the heavier traffic, when these roads are renewed concrete foundations are generally used and the joints are grouted. The older type of road had a life of from 15 to 20 years.

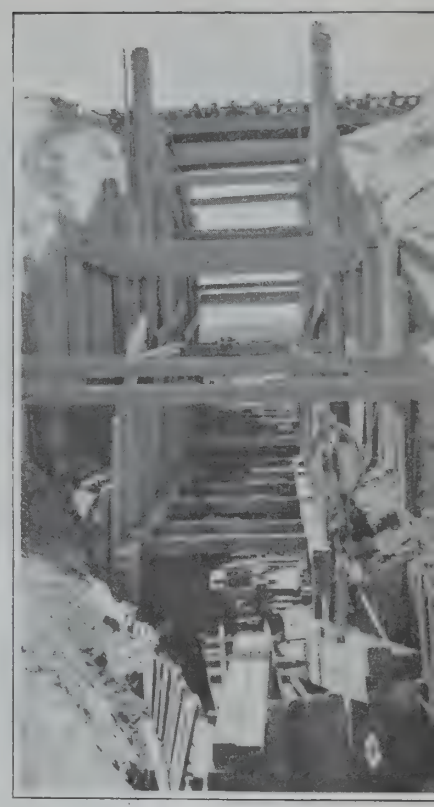
Some tar-macadam has been used, but on the whole stone-block construction is preferred. Just now, because of the shortage of block, considerable waterbound macadam is being laid as an emergency measure. Concrete has been laid only in experimental sections and conclusions regarding it have, apparently, not been drawn. For stone block, porphyry is preferred, except on grades where a hard sandstone, called *grès*, is used. The latter is gritty and gives a better foothold than porphyry.

A Belgian road-roller driven by a gasoline engine

The accompanying illustration, for which we are indebted to *Engineering News-Record*, shows a small road roller employed on Belgium highways. This machine is driven by a gasoline engine on the shaft inside the roller, and is steered by the smaller roller. The operator walks at the rear, with his hands on the control members at the end of a shaft.

## Impact Tests to Determine Highway Wear

THE Bureau of Public Roads of the Department of Agriculture has undertaken an important series of impact tests which are expected to establish in what degree motor truck traffic wears highways. These will continue over a considerable period of time. Statement is made that preliminary road impact tests indicate that the impact pressure exerted by a power truck in motion is about six times greater than that of a truck at rest.

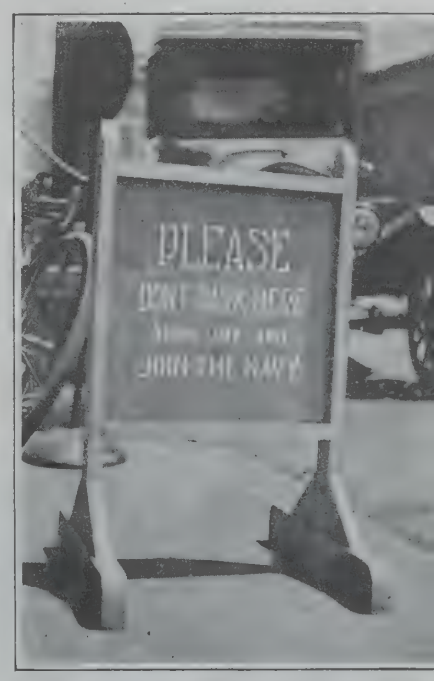


Looking through the excavation made for a draining culvert

The tests were conducted with a clas B Government truck loaded up to 5 tons running up to 15 miles an hour and al lowed to fall from varying heights o the impact measuring apparatus. Thes tests will be continued with trucks rang ing from the lightest weight to th heaviest until complete data is obtained The question of the relative impact ex erted by trucks with solid versus gian pneumatic tires will also be investigated

## A New Way of Advertising the Navy

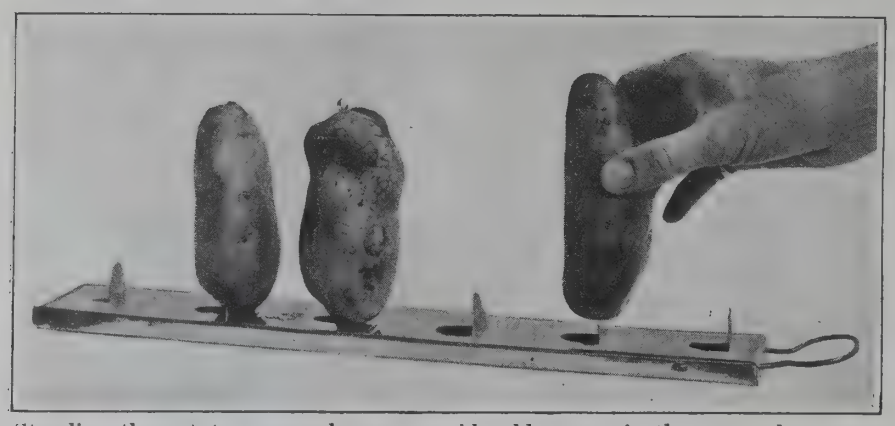
WOODEN tablets, painted navy blue bearing the words, "Please don' park here. Shove off and join the navy, are now placing the iron "No Parking shields issued formerly by the polic department at Minneapolis, Minn. Thes signs are installed at the "no parking zones along the sidewalk in front o certain buildings. The same colore tablet, fastened to a post, is used fo a lawn sign on Government plots. Thi latter reads: "Please keep off th grass. If you want to roam, join th navy."—By *H. Lindquist.*



Minneapolis has found a new "no-parking" sign and Navy recruiting appeal combined

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



**Standing the potatoes on end saves considerable space in the oven when space is at a premium**

## An Idea That Saves Oven Space

IT is economy to have an oven dinner occasionally. And the potato baker shown in the above illustration takes up less oven space by baking the potatoes in a perpendicular position. The tin baker holds six fair-sized potatoes, all of them being removed at one time and without burning the hands.

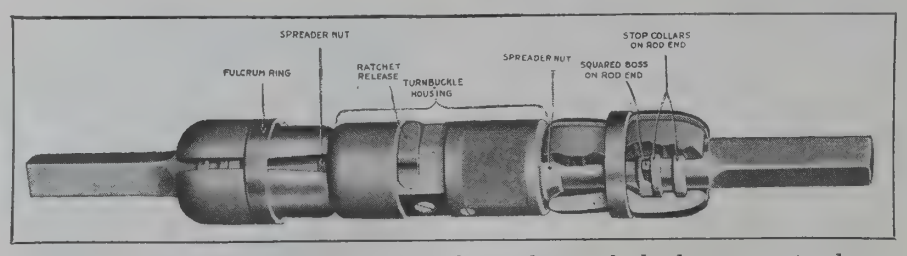
## A Step Forward in Coupling Drilling Rods

OWING to the unreliability and great loss of time involved in present practice, the joining of threaded male and female rod-ends has been a source of continuous annoyance to drillers and the men operating deep-well pumps.

However, by means of the newly-ented device herewith depicted a tight joint of sucker-rods or drilling poles can, within a few seconds, be accomplished in a reliable and more efficient manner than by the former way of screwing them together. And the latter was no easy task, considering that the lengths of rods and poles vary from 20 to 25 feet. This new rod coupling is constructed on practically the same principle as the hose coupling described in the SCIENTIFIC AMERICAN of June 5, 1920.

As may be seen from studying the illustration, a quick, tight and reliable joint can easily be obtained by allowing the squared boss-ends of the rods to slip into the squared sockets of the connecting shaft of the coupling, and by applying an ordinary wrench to the hexagonal recess of the turnbuckle-housing. The rods are, therefore, and without being turned, drawn together until their stop-collars are firmly seated on the stop-collars of the connecting shaft. The unscrewing of the turnbuckle during pumping or drilling operations is made impossible by means of a small ratchet inside of the housing, preventing same from turning backward, unless purposely released.

By the use of this new system of coupling invented by John Arthur Weis of New York City, rods can be lowered in a bore-hole or pulled in less than one-third of the time formerly needed, wherefore this style of coupling will be of greatest interest wherever poles or rods are extensively used, especially in deep well drilling and pumping.



**The new coupler for drill rods and sucker rods, partly broken away to show the coupling members**

**A slot in this tool permits of running oil between the spring leaves**

## A Handy Spring Oiler

THE oiler illustrated at the left has recently been patented. It is a most ingenious tool and will be found quite handy when working on an automobile. It is a combination oiler and wrench, and when used for the former purpose it is driven in between the leaves of the spring, preferably in the center. Its end is tapered, thus making insertion easy. Oil when applied runs down the grooved portion which is carried back about three inches from the tapered end, as shown.

## Moving a Bungalow by Motor Truck

WHEN the average citizen moves his home he hires a truck or a cart or wagon and several experienced able-bodied furniture manglers to do packing and loading and unloading and setting up, and confidently expects that at least half of his property will be serviceable when he is "settled." This is because the average house is owned by others or is too weighty or bulky to be taken along with the furniture.

But seemingly the ideal removal was made a short time since by a San Diego, Cal., resident, who was dissatisfied with his location. He bought a property four miles distant and because his bungalow suited him perfectly he wanted to set this up on the new lot. Removing it appeared difficult, but an enterprising truckman decided it was a practical undertaking. The building was mounted on wheels and with a big truck it was hauled over the road in six hours. From this it is evident that the bungalow has advantages that largely compensate its disadvantages when one wishes to move from one locality to another.

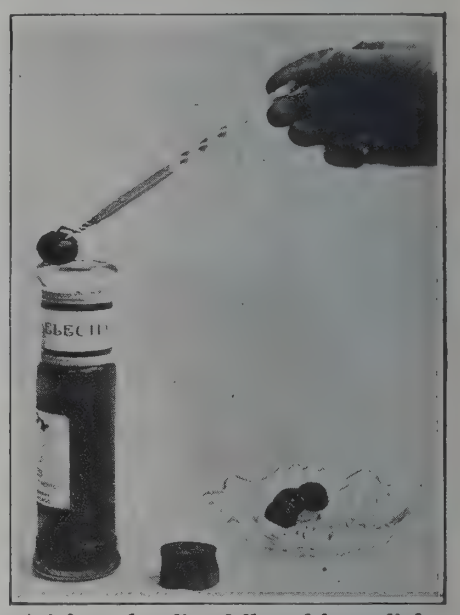
## A New Kink in Olive Forks

ONE of the simplest olive forks yet brought to our attention is that illustrated at the right. On the end of a long handle are two prongs, one of which is straight while the other is slightly curved. By piercing an olive with the straight point and giving the handle a slight twist, the curved prong catches the olive and prevents it from falling back into the bottle.

## Taking the Dirt and Trouble Out of Small Power Plants

A SELF-CONTAINED electric lighting plant that has the appearance of a piece of steel furniture, together with a highly-finished cabinet to house the battery, the combination adding to the appearance of any home, yacht, or wherever it may be placed, has just been brought out. It puts to shame the unsightly, oil-bespattered engines and open, dust-littered battery cells that are so common.

But, in addition to the appearance of the new electric unit, it employs what is undoubtedly the most handy feature ever used in a lighting plant. This is called the "Control Case"—a drawer which contains all of the vital electrical mechanism, instead of the usual multiplicity of meters, fuses, switches, etc., mounted on an open board. This "drawer" slides in and out the same as a drawer in any table or desk. If any trouble occurs one simply pulls out this drawer and slips another in its place, and the trouble is ended.

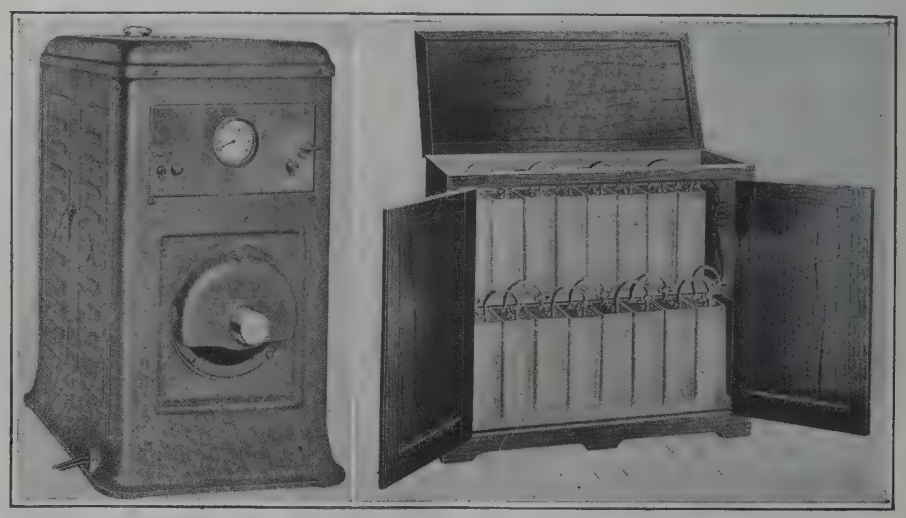


**A jab at the olive followed by a slight twist does the trick**

## Heating Dwelling Rooms with Acetylene

WE learn from the Bulletin of the Swiss Acetylene Society that the heating of dwelling houses by means of acetylene instead of coal is being strongly urged because of its great economic advantages. Enthusiasts, indeed, declare that we are about to enter upon a new period of domestic heating. Less service is required to handle the furnace and the time required for heating the building is less. In the Palace Hotel at Lausanne, a central heating system making use of acetylene has been in operation for several months, and is said to give great satisfaction. The building consists of a block of five houses, and to secure a temperature of 10° C. or 50° F., 400,000 calories are required, which requires the combustion in the middle of winter of 800 km. of coal per day. In mild winter weather this hotel can be kept very comfortable by the daily consumption of from 100 to 200 km. of carbide.

The acetylene is produced in a stationary acetylene apparatus mixed with air, and burned in a coil system. The entire hot water system to serve the five houses can be heated in 20 minutes to a temperature of from 70 to 80° C. or 158 to 176° F. Satisfactory precautions for entire safety of operation are of course fully guaranteed.



**Two cabinets of steel contain the engine, generator, and storage battery, thus eliminating dirt and trouble**

# Opening the Shortest Pathway to the Brain

IT is the prolonged dusk of Arctic night one hundred miles above the Circle—the thermometer far below zero and snow piled mountains high. A crowd of unlearned but eager Lapps, too numerous for the small mission chapel nearby, are assembled in the open air on skis and snowshoes—their eyes centered on a crudely erected screen of snow.

Across this screen, as white as Nature can make it, flashes a succession of vivid pictures—Japan, China, Korea, tropical India, all imaged on that Arctic background—pictures of climes and peoples that benighted audience had never dreamed of. And the source? A simple but efficient little stereopticon, the Balopticon, mounted on a rough table in the snow and covered with a heavy, protecting blanket, that its lenses may not break in the frigid atmosphere.

This true incident is perhaps unusual, but no more significant than countless other instances of Balopticon service. Optical projection has broken down the travel barriers to a knowledge of the earth. Photography and projection co-operating bring the world to our feet, for whatever can be photographed anywhere can be projected in life-like reproductions anywhere else.

And so in church and mission, school and college, lecture hall and home, wherever people of any race or creed gather together, the Balopticon has made its enlightening way, adding to the sum total of human knowledge as no other agency can. For the eye is the gateway of the shortest nerve path to the brain. What the eye sees, the brain comprehends quickest and remembers longest.

In its development of the Balopticon to represent the most complete and efficient line of projection apparatus obtainable, the Bausch & Lomb Optical Company has but further enriched its seventy years of service—of supplying practically every form of lens or optical instrument that humanity needs in its search for truth and knowledge.

# Sawtooth Correctly Used

"Today—the Sash makes the Factory"

THE sawtooth roof is no cure-all for bad light and ventilation: there are right and wrong ways to use it.

The *wrong* way is over *any* low, very wide building needing much light and air. A machine shop thus treated is a lost opportunity in design.

The *right* way is an *auxiliary* feature, on a building narrow enough and high enough to permit light from the sides to reach past the centre. The building shown below illustrates this. Even when it is filled with machinery, there will be no hampering shadows, no objectionable contrast of light and shade, to make clear vision difficult.

The sawtooth is rarely the *best* roof for any purpose; but it is far better than a solid roof, and its exclusion of all direct sunlight is an advantage for certain limited uses.

As manufacturers of LUPTON STEEL SASH PRODUCTS, we are glad to advise our customers on the best arrangement of building and sash to get maximum results. No charge is made for this service.

Write for leaflet, "The Case of the Sawtooth Roof." It tells *where* and *how* to use the sawtooth for good results, and what to use where the sawtooth's limitations render it unsuitable.

## Our Lagging Gold Production

(*Continued from page 628*)

closing down. The principal causes of decline in gold mining in this country are the high wages, the decreased efficiency of that labor and the great increase in the cost of supplies. Since the outbreak of the war, prices of all commodities have increased greatly except that of gold, which as the standard of value is fixed at $20.67 per ounce. In other lines of activity where the cost of production increased the manufacturer could raise the price to be paid for his particular product to meet the excess cost, but the miner could only obtain $20.67 for an ounce of gold, even though the cost of producing it had doubled. Under the circumstances many mines have been compelled to close and await more favorable conditions. Those mines that have continued operations have been able to do so only by practicing the most rigid economies and by the curtailment of development work. The increased freight rates and car shortage have seriously interfered with the production of those mines compelled to transport their ore by railroad to distant smelters, and in the case of the dredging companies in California and Oregon the shortage of electric power has been so great that they were compelled to suspend operations entirely for several months in the summer or "dry" season, or else to operate under a decreased schedule, which raised their operating costs to a point where it was no longer possible to mine at a profit. Many dredges have been started in districts where the successful operation of the boat depends primarily on low running costs, and a large yardage, for there is only a certain value in each cubic yard of gravel and it must be extracted at a cost below that value if a loss is not to be sustained. The adding of a cent or two to the cost of handling a cubic yard of gravel often wipes out the margin of profit. Many of the smaller dredging companies found it necessary to shut down their operations, but the big ones, running a number of boats, find it so necessary to keep their trained men together that they cannot afford to suspend, and these companies have continued producing gold at the expense of greatly diminished profits.

To meet the situation confronting the gold miners in the United States a number of suggestions have been made for protecting them against adverse economic conditions. It has been suggested that a bonus per ounce be given to gold producers until such time as economic conditions will return to normal. The American Mining Congress and many other public organizations have adopted resolutions calling upon the Government to pass some legislation favorable to the mining industry, but to date these plans have not passed beyond the talking stage.

In connection with the suggested bonus on gold it is interesting to note that the same subject is being brought to the attention of the authorities in South Africa and Australia, and is now under discussion in England. The British Government has appointed a committee of experts to make a sweeping inquiry into the conditions at gold mines and to suggest possible measures of relief. Especial attention is being given the desirability of granting the demands of the gold producers for a revision of the selling price of their product to compensate for the increased cost of labor and supplies, to means of encouraging the mining of low-grade ores, and of stimulating the production of gold in general. According to a statement issued by the Chairman of the Transvaal Chamber of Mines, out of 46 companies operating in the Transvaal, 6 were running at a loss and 15 were barely paying expenses, and it is said that a large number of the mines on the Rand will have to shut down unless given some relief.

## The North Platte Project Today

(*Continued from page 629*)

after the river flows eastward a hundred miles or more to the land just opened for settlement the average elevation in the vicinity is about 4,100 feet above the sea-level. The stream was naturally a turbulent one and subject to enormous fluctuations in flow. At one time, there would be a devastating flood; at another, the old settlers would have difficulty in getting enough water to keep the crops alive. The excess water of the one season, though needed later on, simply went to waste. The lands now under irrigation had a normal value of about $1.25 per acre and served principally as grazing land over which cattle and sheep roamed with their attendant keepers. Now, the irrigated ranches are bought and sold at $150 to $200 per acre, and have a rental value per acre per year of $15 to $25. These are not land-boom values, but prices paid by one experienced settler to another. The sugar beet crop totals about $1,000,000; the potato crop another $1,000,000. Alfalfa attains a value equal to both combined. Wheat, oats, barley and maize are regular standard products. The country is so well-to-do that "automobiles on the country road are so thick that speed laws are unnecessary." It is claimed, in fact, that the agricultural value of these lands is probably as high as that of any other section in the country, with the possible exception of the fruit districts of California, Washington and Oregon. So, then, the cow and sheep country has not been turned into land that is moderately valuable, but into land that is comparable with the best there is.

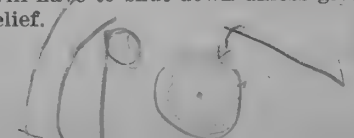
The North Platte project is a one-river enterprise. That is, it involves only a single general watershed. Naturally, minor rivers and streams tributary to the main river are to be included. The irrigated district lies partly in eastern Wyoming and partly in Nebraska. Near the boundry line between the two States, a subsidiary dam was placed. This structure is a diversion dam. The result has been a connection with two of the largest canals in the West. Each is 125 miles long and serves, or will serve, 100,000 acres.

The temperature in the various parts of the irrigated district naturally varies because of a difference of conditions. However, in the Fort Laramie region at an altitude of three-quarters of a mile, the mercury goes down to 30 below and up to 104 above zero, F. The irrigation season runs for six months, beginning April 1. But canals may have to be operated in winter time for other reasons. Thus, the Lingle Power Plant in Wyoming depends upon Platte water for its operation, and the City of Torrington depends, in turn, more or less upon this plant for lighting current. Naturally, such demands require winter operation of canals. The daily average of current supplied, in winter, seems to be around 700 kw-hrs.

## How Hard Is a Rock?

(*Continued from page 629*)

The grip containing the specimen is then removed, brushed free from dust, and weighed. By the use of small metal washers, one or more of which may be slipped over the projecting rod of the grip, the initial weight is adjusted to exactly 1,250 grams. Forthwith, the grip is replaced in the same position as previously and the machine given 1,000 revolutions, 30 to the minute. The material is again weighed, the tests being repeated with specimens reversed as a method of ascertaining the average hardness of the two ends. The one-fourth inch opening in the funnel of the hardness machine will consume 18.5 pounds of sand during the test. The coefficient of hardness for varying types of rock will range from 19.7 for the hardest specimens of quartzite to 0 for extremely soft limestones and sandstones.



## LEGAL NOTICES

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

SCIENTIFIC AMERICAN PUBLISHING CO., Woolworth Bldg., New York

The magnitude of the road-building program in the United States is partially reflected by the demands being placed upon the hardness machine, tests being made at a rate of about 600 a year. Samples of road-building rock are tested without expense for any citizen by the Office of Public Roads and Rural Engineering, Washington, D. C., printed instructions being furnished as to the regulations governing the submittal of samples of material. Abrasion, water absorption, toughness, cementing value, and compression tests are conducted as well as scientific experiments determining the hardness of rock.—By *S. R. Winters.*

## Why the Cliff-Dwellers Vanished

(*Continued from page 630*)

change of work. Under primitive conditions all of this was wanting and it is, therefore, a safe assumption that the disastrous consequences of dust inhalation have been one of the most important contributory causes of an excessive death rate, leading ultimately to race extinction.

Without enlarging for the present purpose upon further details, it is sufficient to have emphasized one of the possible additional reasons, not heretofore advanced, why this ancient civilization should have come to an end. How large that population was is now, of course, but a matter of mere conjecture. According to Prudden, there is no reason for believing that the number of rooms in any district affords an exact indication of the populousness of the region at any one time, because the present condition of the ruins seems to point to very great differences in age. When the Old North Pueblo of Pecos was discovered by Coronado in 1540, it was described as to contain from 2,000 to 2,500 inhabitants. By 1797 the population had decreased to 89, which by 1838 had been reduced to a remnant of only "a dozen or so." (P. 38, Archaeological Institute of America.) It might be possible by estimates based upon the number of rooms in this ruin to arrive at some conclusion as to the probable density of population at a period when, however, the true cliff-dwellers had probably long been extinct. The South House at Puye, described by Morey, contains 173 rooms, which, assuming four persons to a room, would give about seven hundred inhabitants. But it is impossible today, due to destruction and decadence, to estimate with accuracy the probable number of rooms used for residential purposes, and nothing, of course, is known as to the approximate number of inhabitants.

If there is so much uncertainty as to the number of ancient inhabitants, there is somewhat less doubt as to their bodily proportions. Unfortunately, far from enough has been made of the skeletal remains that have been discovered and over-emphasis has been placed upon cranial measurements, much less important than bodily proportions for really practical purposes. Morey in his report on the "Cannon-ball Ruins in Southwest Colorado" describes three entire skeletons, assigning to the femur a proportion of 27 per cent of the entire length and determining the stature of the three at 5 ft. 2 in., 5 ft. 3 in., and 5 ft. 4 in., respectively; or all under 5 ft 6 in., and while he admits that these values are probably a little low, he remarks that "even discounting the slight shrinkage which invariably takes place between the living body and the skeleton, the heights thus attained are approximately low." This conclusion seems justified in the light of other measurements, all indicating that the average stature of the builders of these structures was "considerably below that of our own race"; and this is true also for the Pueblo, Zuni, and Hopi Indians of today.

Without, therefore, arguing the question as to the probable numbers of the ancient population and the rate of decadence during the historic period as possibly deter-

# Standardize on Duracord

HUNDREDS of firms throughout the United States in every line of industry have adopted Duracord as their standard portable electric cord for all purposes.

In most cases, these users started with a small amount of Duracord and watched results. Its thick, heavy *woven* covering established a record of endurance that brought forth the edict "Standardize on Duracord".

*This is Duracord. Thick, heavy strands, woven like a piece of fire hose, not braided. Picture shows outside covering only with impregnating compound removed.*

*Here is the ordinary braided cable covering. Note the open and porous construction, easily cut, stretched or unraveled. Compare it with the illustration of Duracord above.*

**Duracord is made in 23 sizes**

to fit all kinds of portable electric tools, extension lamps, sand and cement mixing machines, portable loaders, magnetic cranes, mining machines, mine locomotives, welders, storage battery charging outfits—anywhere in fact where portable cord is used.

If you are using Duracord for special work only, check up its service record and ask your electrical jobber for samples of the other sizes of cord you use.

If you have not yet used Duracord ask your jobber or write us direct for samples of Duracord and ordinary cord for you to test and compare yourself.

**A Wrench that IS a Wrench**

To the trained machinist, this picture tells the whole story.

No better wrench than Williams' "W&B" Machinists' Knife-Handle is made. With its head and bar drop-forged in one piece, its jaw of hardened malleable iron, its screw turned from wrought steel, it possesses the quality that distinguishes all of Williams' Superior Machinists' Tools—absolute dependability. It will do the job it was built for, do it well, and keep on doing it indefinitely.

Sizes 6 to 21 inches carried in stock. 2 other patterns also.

**LEFAX**
**The Loose-Leaf Pocket Cyclopedia**
**Compiled by Yourself for Your Own Use**

All those who are unfamiliar with the "Lefax System" should send at once for a free circular, illustrating the loose-leaf data books which are adapted to contain printed data sheets, plus your own memoranda. There are dozens of special data sheets that can be had in related subjects at 50c and $1.00 each and there is no duplication. Each 50c set contains 20 sheets and each $1.00 set contains 50 sheets or 40 and 100 pages respectively. Blank and ruled forms are provided and are almost endless in number.

A set of 40 leading sample blanks is 25c. A complete set of samples is 75c. We also supply binders and other items. Our circular is free for the asking and we are ready to make prompt delivery of binders and data sheets from stock.

SCIENTIFIC AMERICAN PUB. CO.
233 Broadway New York

mined by existing ruins, it would seem that the conclusion is justified by the known facts, that this population was quite extensive, but at the time of its decadence, below average stature, possibly indicative of undernourishment, which, with the indicated continued exposure to health-injurious dust, would lead to the further conclusion that an excessive mortality rate, more probably than any other extraneous cause, gradually led to an excess of deaths over births, and a vanishing population, of which the remnants found shelter and new homes among the Pueblos farther to the south, possibly as far as northern Mexico.

This conclusion, which as far as I know, has not heretofore been advanced, is also supported by another fact of not inconsiderable importance. The extensive and unusual development of the pottery industry among these people also represents a dusty and health-injurious occupation, which under given conditions would be certain to prove detrimental to life and health. The subject is, therefore, one well worth further consideration and it is hoped that these suggestions may at least result in the scientific ascertainment of the nature of the stone materials manipulated by these ancient people and particularly the chemical and microscopical characteristics of the stone work and masonry, typical of the so-called cliff-dwellings, varying widely, of course, according to the geological formation from southern Colorado and Utah to southern New Mexico and Arizona.

## Disposing of the Sewage

(*Continued from page 632*)

cance of efficient spraying and delivering the sewage in fine showers to trickle through the interstices of the beds and carry fresh supplies of oxygen to sustain aerobic conditions. The beds, otherwise, are apt to become clogged and ineffective.

When, in 1909, the filter beds of the Mount Vernon Works were ready, repeated trials were made of various sprinkling devices in use elsewhere, especially of the cups used at the Experimental Station of Massachusetts. These latter contrivances gave the best results, but it was not until Mr. Boyd Wilkie, now superintendent, devised a cup with a rolled rim, that nearly perfect results were obtained. This cup of rolled metal, three inches in diameter, one inch deep, with a rolled rim, is socketed on a standard eighteen inches high to receive a stream from a ¾-inch nozzle at an elevation of about five feet. Exhaustive experimental tests (*Engineering News*, March 24, 1910) were made, finally giving 92 per cent efficiency in overlapping areas of spray. The secret of the efficiency of the cup is the rolled rim which spreads the spray evenly, over a greater circumference of area than a cup with a sharp edge, and in finer spray.

When the building of the plant was under discussion and before a final decision was reached, in order to satisfy property owners and residents in its vicinity, the engineers were obliged to devise a ventilating system to carry off noxious odors which, in ignorance of the efficiency of properly constructed filter-beds, the public imagined, would be insufferable.

So, at an unnecessary expense of some thirty thousand dollars, twin towers were erected, supplied with electrically-driven fans to draw off, through a system of drums, the noxious gases from the filter sheds and scatter them in the upper air. Of course, there was no appreciable odor beyond the immediate vicinity of the works to be overcome in any such ridiculous way. The device has never been used. The contractors derived the sole benefit of the extra expenditure. At a distance of a hundred yards from the works, no odor is perceptible.

The grounds about the works have been graded and made into the semblance of quite an attractive park and as there are many shade trees on the surrounding terrace, visitors are not loath to take advantage of a rest on park settees provided for their convenience.

## A New American Industry

(*Continued from page 634*)

ingenuity has not been latent in the design of these toys and sales on some recent models have reached enormous figures.

The German toy industry will undoubtedly recover, in a measure, from the paralysis it suffered during the war. But a very different class of toys will have to be sold in this country. There were a few large toy factories in Germany before the war but the backbone of the German toy industry was the individual workman who made toys in his own home, often being assisted by the entire family, marketing his goods through a syndicate. The art of the toy-maker was handed down from father to son through many generations.

The workmanship of these home toy factories is exquisite and it cannot be equaled on a quantity basis. Nor has the American workman the patience to produce such toys at any price. If German labor conditions return to normal, undoubtedly her home toy producers will again be a factor.

As an example, there were recently imported from Germany by a large toy dealer five large models of a great ocean liner. They were perfect in every detail and although they sold for $150 each, they were gone within a few days after being placed on display in New York. The boats could not have been made for that sum in this country.

The situation of our new toy industry is effectively summed up by a New York toy merchant and manufacturer in these words: "Before the war I would have believed it impossible to get along without the German toys. They were the backbone of every toy display. The few American toys were rather shabby and they were just 'fillers' in the line. I tried for years to put a line of American-made mechanical toys on the market without success simply because the toy buyers would not give the line a chance. That was just the trouble. It wasn't that we were not able to make toys as well as anyone else, but that no one would buy them. The war gave us the chance and we have never missed the German toys from our shelves. There will be some toys imported, we may be sure, but the foreign toys will occupy about the same place in our market that the domestic toys used to hold."

## The Properties and Uses of Manjak

(*Continued from page 635*)

ular efficacy in keeping such pipes watertight, air-tight, and free from corrosion at the joints, but it also facilitates the work of joining and separating the pipes owing to its lubricating qualities. It has been found much superior to white lead or any other substances previously used for such purposes, and its use results in economy.

The Government of Trinidad is now making use of manjak in painting the under parts of bridges and other structures where protection is required from water. Excellent results have been obtained by using manjak paints and compounds on steel smoke stacks, car trucks, fenders, burrers, and all iron and steel work connected with power-house and car buildings. Their compounds have also been used successfully in the form of insulating varnish on armatures and electrical connections, and on car roofs as a protection from the hot, tropical sun and rain. In general, where a good insulating material is required against heat or electricity, the value of manjak is said to be exceeded only by rubber and glass.

# Man alive— Listen!

## You can smoke Camels till the cows come home without tiring your taste!

CAMELS bring to you every joy you ever looked for in a cigarette! They are so new to your taste, so delightful in their mellow mildness and flavor, and so refreshing, you will marvel that so much enjoyment could be put into a cigarette!

To the most fastidious smoker, ***Camels are a revelation!***

Camels quality is as unusual as Camels expert blend of choice Turkish and choice Domestic tobaccos ***which you will prefer to either kind of tobacco smoked straight!*** No matter how liberally you smoke, Camels never will tire your taste!

You will marvel at Camels smooth body. And, your delight will also be keen when you realize that Camels leave no unpleasant cigaretty aftertaste nor unpleasant cigaretty odor.

For your own personal proof, compare Camels with any cigarette in the world at any price.

*Camels are sold everywhere in scientifically sealed packages of 20 cigarettes for 20 cents; or ten packages (200 cigarettes) in a glassine-paper-covered carton. We strongly recommend this carton for the home or office supply or when you travel.*

# Camel CIGARETTES

R. J. Reynolds Tobacco Co.
Winston-Salem, N. C.

# . . . *and at* famous ocean playgrounds

## *A fact:*

Fatima is steadily the largest-selling cigarette at all of these (and other) fashionable resorts:

*Atlantic City*
THE NEW AMBASSADOR
THE BREAKERS
THE MARLBOROUGH-BLENHEIM
THE TRAYMORE

*Long Beach*
THE NASSAU

*Narragansett Pier*
THE CASINO

*Palm Beach*
THE BREAKERS

—and even at the exclusive NEWPORT CASINO, Fatima's sales are equalled by those of only one other cigarette—an exceptionally high-priced brand.

Liggett & Myers Tobacco Co.

# FATIMA

*A Sensible Cigarette*

*For a real reason—*
*"Just enough Turkish"*

Expensive, straight Turkish cigarettes contain *too much* Turkish for steady smoking. They are over-rich and heavy. And many Turkish blends contain *too little* Turkish. They are disappointing in taste. Fatima, on the other hand, contains *"just enough Turkish"*—just enough to please the taste without raising any question of "how many."
